ABSTRACT

This report presents the results of an environmental life cycle assessment (LCA) on a house modeled with two types of exterior walls: a wood-framed wall and a lightweight concrete masonry unit (CMU) wall. The LCA was carried out according to the guidelines of the ISO 14040 series. The house was also modeled in five cities, representing a range of U.S. climates: Tampa, El Paso, Knoxville, Providence, and Detroit.

The house is a two-story single-family building with a contemporary design. The house system boundary includes the inputs and outputs of energy and material from construction, occupancy and maintenance. The life of the house is 100 years.

The LCA was conducted by first assembling the relevant LCI data from published reports and commercially available databases. The LCA software tool, SimaPro, was then used to perform a life cycle impact assessment. Impact assessment is not completely scientific; so three different methods were used: Eco-Indicator 99, EDIP/UMIP 96, and EPS 2000. Further, three versions of the Eco-Indicator 99 method were used—each one reflects a different cultural perspective: hierarchic, egalitarian, and individualist.

The data show similar results for the two houses. In most cases the lightweight CMU house has lower (better) impact indicators in the colder climates (El Paso, Knoxville, Providence, and Detroit). In the warmest climate (Tampa), the impact indicators are generally greater (worse) for the lightweight CMU house because household energy use is also greater. The exceptions are (i) in the categories “respiratory inorganics,” “land use,” and “minerals” in the Eco-Indicator methods and the categories “life expectancy,” “severe morbidity” “severe nuisance,” and “species extinction” in the EPS 2000 method, where impact indicators for the lightweight CMU house are greater, and (ii) “radiation” and “ozone” in the Eco-Indicator methods and the categories “ozone depletion,” “ecotoxicity,” and “human toxicity, water” in the EDIP/UMIP 96 method, where indicators for the wood house are greater.

The most significant environmental impacts are not from construction products but from the production and household-use of electricity and natural gas. Furthermore, the largest impacts are in the form of depletion of fossil fuel reserves (categorized as damage to natural resources) and release to the air of respiratory inorganics (categorized as damage to human health). Among the construction products used in the house, wood products have the largest environmental load, followed by cement-based materials for the lightweight CMU house, and followed by copper tubing then cement-based materials for the wood house.

LIFE CYCLE ASSESSMENT OF A LIGHTWEIGHT CONCRETE MASONRY HOUSE COMPARED TO A WOOD FRAME HOUSE

by Medgar L. Marceau and Martha G. VanGeem*

INTRODUCTION

The Portland Cement Association (PCA) has developed environmental life cycle inventory data to evaluate the environmental aspects of various concrete products. The objective has been to promote the environmental benefits of building with concrete. The life cycle inventory of three concrete houses has been published by PCA and others.^[1, 2, 3, 4] Each house has the same layout but they are modeled with different concrete exterior wall systems: insulating concrete forms, concrete masonry units, and lightweight concrete masonry units. These reports constituted the first phase of a life cycle assessment (LCA). Each report presented a comparison between a concrete house and a similar wood-framed house. The reports described the life cycle inventory of the cement-based materials (concrete, concrete masonry units, mortar, grout, and stucco) and the household occupant energy-use that make up the life cycle of a house. This report is one of three reports that present the results of an assessment of the environmental attributes of concrete construction compared to wood-framed construction.

Life Cycle Assessment

Performing an LCA is one way to assess the impacts a product has on the natural environment. The International Organization for Standardization (ISO) has developed international standards that describe how to conduct an LCA (ISO 14040 series). An LCA is a study of the environmental aspects and potential impacts throughout a product's life—from raw material acquisition through production, use and disposal.^[5] The ISO standards describe three phases of an LCA. The first phase is an inventory of the inputs and outputs of a product system. The second phase is the assessment of the potential environmental impacts associated with those inputs and outputs. The third phase is the interpretation of the result of the inventory analysis and impact assessment phases in relation to the objectives of the study.^[5] These three phases are commonly referred to as (i) life cycle inventory analysis, (ii) life cycle impact assessment, and (iii) life cycle interpretation. In this report, “LCA” will refer to all three phases. The LCA in this report adheres to the requirements in the ISO 14040 series. However, there are some technical limitations to LCAs: according to ISO 14041,

The models used for inventory analysis and to assess environmental impacts are limited by their assumptions, and may not be available for all potential impacts or

*Project Assistant and Principal Engineer, Construction Technology Laboratories, Inc., 5420 Old Orchard Road, Skokie, IL, 60077 USA (847) 965-7500, www.ctlgroup.com.

applications. Results of LCA studies focused on global or regional issues may not be appropriate for local applications, i.e. local conditions might not be adequately represented by regional or global conditions. The accuracy of LCA studies may be limited by accessibility or availability of relevant data, or by data quality, e.g. gaps, types of data, aggregation, average, site-specific. The lack of spatial and temporal dimensions in the inventory data used for impact assessment introduces uncertainty in impact results. This uncertainty varies with the spatial and temporal characteristics of each impact category.^[5]

GOAL

The purpose of this project was to determine whether single-family concrete houses have an overall environmental advantage over houses constructed with other materials. To achieve this goal we used life cycle inventory data to conduct a life cycle assessment of two kinds of house: one with a lightweight concrete masonry unit (CMU) wall, the other with a wood frame wall. Information on the target audience for this report and other project reports is presented in Appendix A.

SCOPE

The functional unit in an LCA is defined in ISO 14040 as the quantified performance of a product system.^[6] In this case, the functional unit is one house. The system boundary is the interface between a product system and the environment.^[6] The system boundary of this study is shown in Figure 1. It includes the inputs and outputs of energy and material from construction, occupancy, and maintenance. The system boundary excludes human resources, infrastructure, accidental spills, impacts caused by people, and decomposition of household components after disposal.

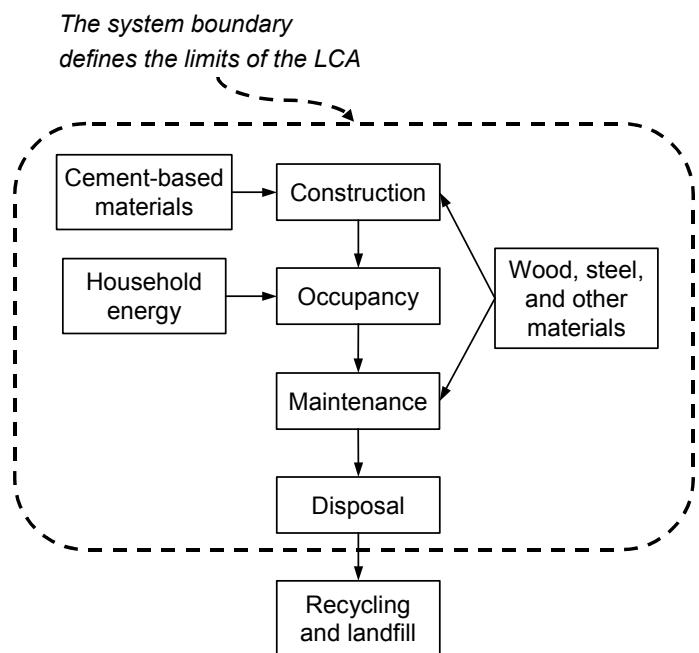

Figure 1. System boundary for house life cycle assessment.

The same layout is assumed for both the wood frame and the lightweight CMU houses. The houses are designed to meet the requirements of the 1998 International Energy Conservation Code (IECC)^[7] because it is the most widely used energy code in the United States. The long-term energy consumption of a building depends on local climate, so the houses are modeled in a variety of regions. Five cities were chosen that represent the range of climates in the United States: Tampa, Florida; El Paso, Texas; Knoxville, Tennessee; Providence, Rhode Island; and Detroit, Michigan.^[8] House energy consumption is modeled using Visual DOE 2.6 energy simulation software.^[9]

The data and data quality requirements are limited by the available data. In general, recent data from North America, representing average technology, is preferred, however, this is not always available. In general, the LCI data include second order system boundaries, that is, primary flows plus energy and material flows including operations.

HOUSE DESCRIPTION

The houses described in this report were designed by Construction Technology Laboratories, Inc. (CTL) and are based on the designs of typical houses currently built in the United States. Each house is a two-story single-family building with four bedrooms, 2.7-m (9-ft) ceilings, a two-story foyer and family room, and an attached two-car garage. Each house has 228 square meters (2,450 square feet) of living space, which is somewhat larger than the 1998 U.S. average of 203 square meters (2,190 square feet).^[10] The size of the houses is based on the average size of insulating concrete form (ICF) houses constructed in the United States.^[11] Figures B1 through B8 in Appendix B present the floor plans and elevations.

The houses were modeled in five cities, representing a range of U.S. climates. El Paso was selected because it is a hot dry climate with large temperature swings where thermal mass is most effective in increasing thermal comfort and in reducing energy use. Tampa was selected because it is a hot humid climate with small temperature swings where thermal mass works almost as well. Knoxville was selected because it is a moderate climate. Providence and Detroit were selected because they are cold climates.

The building envelope in each location was designed to meet the minimum requirements of the 1998 IECC using standard building materials.^[7] The IECC minimum requirements for thermal resistance are presented in Table 1 for each of the five cities where the houses are modeled. R-value refers to thermal resistance in $\text{m}^2 \cdot \text{K}/\text{W}$ ($\text{hr} \cdot \text{ft}^2 \cdot ^\circ\text{F}/\text{Btu}$) and U-factor refers to thermal transmittance, that is, heat flow per unit area per degree, in $\text{W}/\text{m}^2 \cdot \text{K}$ ($\text{Btu}/\text{hr} \cdot \text{ft}^2 \cdot ^\circ\text{F}$). The maximum U-factor is equivalent to the inverse of the minimum R-value. Variations in regional building materials and practices, such as the use of crawl spaces and basements, are not considered in order to simplify the analyses and in order to compare energy use across all cities.

In all cities, the houses are slab-on-grade construction. The slab-on-grade floor consists of carpeted 150-mm (6-in.) thick normal-weight concrete cast on soil. The U-factor of the floor is 1.53 $\text{W}/\text{m}^2 \cdot \text{K}$ (0.27 $\text{Btu}/\text{hr} \cdot \text{ft}^2 \cdot ^\circ\text{F}$). Although the IECC requires perimeter insulation for slabs-on-grade in most areas of the United States, commonly used and accepted energy modeling software cannot model perimeter insulation. Therefore, the slab-on-grade is uninsulated. Second story floors are carpeted wood-framed assemblies without insulation.

In all locations the exterior walls of the wood frame house consist of medium-colored aluminum siding, 12-mm (1/2-in.) plywood, $R_{SI}-1.9$ (R-11) fiberglass batt insulation, and 12-mm

Table 1. International Energy Conservation Code Maximum U-Factors*

Location	Opaque walls**				Roof		Windows***	
	Wood frame		Mass (Lwt. CMU)					
	W m ² ·K	Btu hr·ft ² ·°F						
Tampa	1.107	0.195	1.374	0.242	0.261	0.046	2.7	0.47
El Paso	0.704	0.124	0.818	0.144	0.204	0.036	2.5	0.44
Knoxville	0.602	0.106	0.715	0.126	0.204	0.036	2.3	0.41
Providence	0.517	0.091	0.574	0.101	0.153	0.027	1.7	0.30
Detroit	0.488	0.086	0.545	0.096	0.148	0.026	1.7	0.30

*The maximum U-factor is equal to the inverse of the minimum R-value.

**Calculated based on the design of the houses and the window U-factors prescribed by the IECC.

***The code also requires that windows have a solar heat gain coefficient (SHGC) less than 0.4 in Tampa and El Paso.

(½-in.) painted gypsum board. The exterior walls of the lightweight CMU house in all locations except Tampa consist of 16-mm (5/8-in.) light-colored portland cement stucco, 200-mm (8-in.) lightweight CMU with partly-grouted uninsulated-cells*, wood furring with R_{SI} -1.9 (R-11) fiberglass batt insulation, and 12-mm (½-in.) painted gypsum board. In Tampa, the exterior walls of the lightweight CMU house are similar, except they do not contain any fiberglass batt insulation. In all locations, the nominal weight of the lightweight CMU is assumed to be 1,440 kg/m³ (90 lb/ft³) with U-factors as presented in ASHRAE Standard 90.1-1999.^[12] The wall cross-sections are shown in Figures B7 and B8 in Appendix B.

For both house styles, all exterior garage walls (except the front wall of the garage, which has overhead doors) and the common wall between house and garage are of the same construction as the exterior walls of the house. The front wall of the garage is modeled as a low-mass light-colored wall with a U-factor of 2.8 W/m²·K (0.50 Btu/hr·ft²·°F). Interior walls are wood frame construction and uninsulated.

Roofs are wood frame construction with R_{SI} -5.3 or R_{SI} -6.7 (R-30 or R-38) fiberglass batt insulation. They are covered with medium-colored asphalt shingles.

Windows are primarily located on the front and back façades, and the overall window-to-exterior wall ratio is 16%. The windows were chosen to meet the IECC requirements for solar heat gain coefficient (SHGC) and U-factor. They consist of double pane glass with a low-E coating. To meet the SHGC requirement, windows in Tampa and El Paso are tinted and contain air in the space between panes. Windows in Knoxville, Providence, and Detroit, are not tinted and contain argon gas in the space between panes. It is assumed that interior shades or drapes are closed during periods of high solar heat gains. It is also assumed that the houses are located in new developments without trees or any other form of exterior shading.

Table 2 presents the assembly U-factors used in the analyses. In most cases, using typical building materials results in assemblies that exceed the IECC U-factor requirements.

*Partly-grouted uninsulated-cells means that some lightweight CMU cells are grouted, while others are empty (do not contain insulation or grout). Grouted cells typically contain reinforcing steel. *Partly grouted* is assumed to mean cells are grouted 80 cm (32 in.) on center vertically and 120 cm (48 in.) on center horizontally.^[12]

Table 2. Assembly U-Factors*

Location	Walls				Roof**		Windows	
	Wood frame		Mass (CMU)				W m ² ·K	Btu hr·ft ² ·°F
	W m ² ·K	Btu hr·ft ² ·°F						
Tampa	0.47	0.082	0.92	0.162	0.18	0.032	2.4	0.43
El Paso			0.43	0.076			1.5	0.27
Knoxville				0.15	0.026			
Providence								
Detroit								

*The maximum U-factor is equal to the inverse of the minimum R-value.

**R_{SI}-5.3 (R-30) attic insulation is used in Tampa, El Paso, and Knoxville. R_{SI}-6.7 (R-38) attic insulation is used in Providence and Detroit.

ASSUMPTIONS

In order to create a realistic house model, the following assumptions about occupant behavior and house performance have been made. These assumptions also ensure that comparisons between houses are possible.

Hot water is supplied by a natural gas water heater, which has a peak utilization of 24 liters/minute (2.5 gallons/minute). The hot water load-profile was taken from ASHRAE Standard 90.2.^[13] The heating, ventilating, and air-conditioning (HVAC) system consists of a natural gas high-efficiency forced-air system with a high-efficiency central air conditioner. The efficiencies of the HVAC system components are assumed to be identical in all cities.

The HVAC system is controlled by a residential set-back thermostat located in the family room. The cooling set-point temperature is 24°C (75°F) from 6 AM to 10 PM and 26°C (78°F) from 10 PM to 6 AM. The heating set-point temperature is 21°C (70°F) from 6 AM to 10 PM and 18°C (65°F) from 10 PM to 6 AM.

Occupant energy consumption for uses other than heating and cooling is assumed to be 23.36 kWh/day. This value was calculated from ASHRAE Standard 90.2,^[13] and it assumes the houses have an electric clothes dryer and an electric stove.

Air infiltration rates are based on ASHRAE Standard 62.^[14] The air infiltration rate is 0.35 air changes per hour in the living areas of the house and 2.5 air changes per hour in the unconditioned attached garage. A family of four is assumed to live in each house.

The life of the house is assumed to be 100 years. The maintenance, repair, and replacement schedules for various building components are shown in Table 3.

LIFE CYCLE INVENTORY ANALYSIS

The data used in the LCA comes from a variety of sources. The life cycle inventory data for cement-based materials comes from peer-reviewed published reports and papers published by PCA and others.^[3, 4, 15] The household energy models also come from a PCA report.^[8] All other data comes from the databases in the commercially available LCA software tool, SimaPro.^[16]

*A new layer of shingles is added every 20 years, and every 40 years the existing layers of felt and shingles are replaced with a new layer of felt and shingles.

A brief description of SimaPro and the LCI of each house are listed in Appendices C and D. Table 4 shows which database is used for each building material. North American data were used whenever available. A brief description of each material is given in Table 5, along with the assumptions that were made. Table 5 indicates that not all data sources are for building materials. In these cases, data for building materials were not available so we used the best available data. The life cycle inventory analysis combines the data from the PCA LCI reports and SimaPro. The LCI of each house is listed in Appendix C (SI units) and D (U.S. customary units). The results do not include waste scenarios or waste treatment.

Unfortunately, not all materials in the houses could be incorporated into the LCA because some materials were not represented in the available databases. However, these materials constitute a minor fraction of the mass of a house, and they represent components that are used in similar amounts in the two houses. The materials excluded are listed in Table 6: notably, gypsum wallboard, floor carpet and under-padding, and roofing materials.

Table 5. LCI Data and Assumptions

Material or energy	Description and assumptions
Aluminum	Process copied from Franklin database. The Franklin data is based on the material and energy requirements and process emissions for the production of aluminum cans with no recycled content, using average USA technology from the late 1990's. For this report, it is assumed that the LCI of aluminum siding is similar to the LCI for aluminum cans. Although the energy to form cans is included, the energy to form the siding is not. This assumption does not introduce a large error.
Cement-based materials	All assumptions can be found in Reference 15. For upstream profiles of electricity and fuels, see below. Combustion emissions of fuels are accounted for in the referenced reports.
Copper	Process for producing copper copied from IDEMAT database. The copper LCI is based on open mining (%4) and sulfide ores (0.6% Cu), delivered to Rotterdam, world average data for 2000, 13% old scrap, and 98% recovery. In this report, it is assumed that the energy required to extrude copper to make pipes is similar to the energy required to extrude aluminum.
Electrical wire	Electrical wire LCI is built up from (i) material and energy inputs from IDEMAT database (copper, PVC, and extruding PVC), (ii) furnace gas used for copper beam production, and (iii) electricity used to manufacture a wire from a copper beam. Data taken from Data Archive database.
Expanded polystyrene insulation	Process copied from Franklin database. The data is for the material and energy requirements and process emissions for the production of expanded polystyrene food containers using average USA technology from the late 1990's.
Fiberglass insulation	Process copied from IDEMAT database. The data is for the production of glass fibers based on the average of 6 industries in the Netherlands. However, the LCI does not include the energy to form batt insulation.
Galvanized steel and other sheet metal	Process for producing sheet steel copied from Franklin database. The Franklin data is based on the material and energy requirements and process emissions for the production of steel using basic oxygen furnace with average USA technology from the late 1990's. For this report, it is assumed that the LCI of sheet steels, like sheet metal, galvanized steel, and truss plates, is similar to that for tin-coated steel strips for beverage cans. This is a conservative assumption because more energy is used to make steel for beverage cans because it is rolled much thinner.
Linoleum	Process copied from IDEMAT database. Data for linoleum made from linseed oil, natural resin and tall oil, a waste product of the paper industry.
Paint	Process copied from ETH-ESU database. Data is for total aggregated system inventory.
Plywood and wood sheathing	Process copied from ETH database. Wood board LCI includes total aggregated system inventory.
Polyester fabric	Process copied from IDEMAT database. LCI for dyed, manufactured polyester fabric, average data.
PVC	Processes copied from IDEMAT database. Inputs and outputs associated with the production of general purpose PVC granulate in Europe averaged over all the polymerization processes. Also included is the LCI for the extrusion of PVC pipes, excluding production of resin, including transport to converter and packaging. Data obtained from three suppliers in the Netherlands. Also included is the LCI for injection molding of PVC fittings for drainage pipe systems. Data obtained from two factories in France with a total annual production of 9000 metric tons.

Table 5. LCI Data and Assumptions (continued)

Material or energy	Description and assumptions
Steel	Process for producing non-sheet steels copied from IDEMAT database. The data is based on world average production and delivery in Rotterdam for 1999. These steels are low cost, general-purpose steels that have excellent welding characteristics. They are usually less suitable for machining. For this report, it is assumed that this is the process for making reinforcing steel and steel angles, and all non-sheet steels like anchors, bolts, pipes, etc.
Tile	Process copied from ETH database. Ceramics production based on total aggregated system inventory.
Windows	Window LCI is built up from material and energy inputs from IDEMAT database (pine, PVC, and extruded PVC) and ETH database (glass).
Wood framing, treated wood, and miscellaneous wood	Process copied from IDEMAT database. The LCI is for the production of rough sawn beams imported from North and Central America, and transported to the Netherlands (6,200 km by ship and 250 km by trailer). Furthermore, 72% is imported sawn and 28% is processed in the Netherlands. The LCI for treated wood may be not be conservative because it does not include the production and use of arsenic-, chrome-, or copper-based preservatives.
Coal	Data for the cradle-to-gate resource requirements and emissions for providing coal as a ready input in electric utility boilers using average USA technology from the late 1990's. Combustion emissions are not part of this process.*
Distillate fuel oil (also called diesel fuel)	Data for the cradle-to-gate resource requirements and emissions for the provision of diesel fuel for use in combustion using average USA technology from the late 1990's. Combustion emissions are not part of this process.*
Electricity	Data for the fuel consumption associated with the generation and delivery of an average kilowatt-hour in the USA using average USA technology from the late 1990's. The LCI includes adjustment to account for line losses.
Gasoline	Data for the cradle-to-gate resource requirements and emissions for providing gasoline as a ready input in tractor trailer engines using average USA technology from the late 1990's. Combustion emissions are not part of this process.*
Liquefied petroleum gas (also called light petroleum gas)	Data for the cradle-to-gate resource requirements and emissions for providing liquid propane as a ready input in industrial equipment using average USA technology from the late 1990's. Combustion emissions are not part of this process.*
Natural gas	Data for the cradle-to-gate resource requirements and emissions for providing natural gas as a ready input in industrial boilers using average USA technology from the late 1990's. Combustion emissions are not part of this process.*
Petroleum coke	Process copied from ETH database. The LCI is based on the total aggregated system inventory. It includes building and working materials, construction of the plants, energy requirement, production waste as well as emissions to air and water and land use. Special attention is given to the emissions of hydrocarbons (both to air and water) of coking plants. Energy is delivered by a pure coal coke boiler (not considering other energy carriers such as sewage sludge or blast furnace gas).*
Residual fuel oil	Data for the cradle-to-gate resource requirements and emissions for providing residual fuel oil as a ready input in industrial boilers using average USA technology from the late 1990's. Combustion emissions are not part of this process.*

*Combustion emissions are included in the house LCI.

Table 6. Materials Excluded from the LCA because of Insufficient Data

Material	Wood		lightweight CMU	
	Amount		Amount	
	kg	lb	kg	lb

Percent of total mass excluded from LCA	19		10	

Household Occupant Energy-Use

Visual DOE 2.6 energy simulation software is used to model the annual household energy consumption.^[9] This software uses the United States Department of Energy DOE 2.1-E hourly simulation tool as the calculation engine. It is used to simulate hourly energy-use and peak demand over a one-year period. Programs that model hourly energy-use are more accurate than other methods, especially for buildings with thermally massive exterior walls, such as lightweight CMU systems. Because heating and cooling load vary with solar orientation, the houses are modeled four times: once for each orientation of the façade facing the four cardinal points (north, south, east, and west). Then the total energy consumption for heating, cooling, hot water, and occupant use is averaged to produce an energy consumption that is independent of building orientation. The annual occupant energy-use is presented in Table 7.

The data presented in Table 7 show that, in each of the five climates, the lightweight CMU houses have similar occupant energy use as the wood frame houses. These results were expected since the lightweight CMU houses and the wood frame houses were designed with standard materials needed to meet IECC requirements. Wood frame walls have R-values that range from approximately 5 to 140% in excess of IECC requirements, while lightweight CMU walls have R-values that range from approximately 0 to 90% in excess of IECC requirements.

An important difference between the two houses is that the system capacity for heating, ventilating, and air-conditioning is less for the lightweight CMU house than for the wood frame house. Table 8 shows the HVAC system requirements as determined by the energy simulation software. The thermal mass of the lightweight CMU house moderates temperature swings and peak loads, and results in lower HVAC system requirements.

Natural gas fired high-efficiency forced-air furnaces are typically available in 20 kBtu/hr capacity increments (equivalent to 5.9 kW) and high-efficiency central air conditioners are typically available in 6 to 12 kBtu/hr ($\frac{1}{2}$ to 1 ton) capacity increments (equivalent to 1.8 to

Table 7. Annual Occupant Energy-Use by Location

Location	Variation	Annual operating data				
		Electricity		Natural gas		Total energy, GJ
		GJ	kWh	GJ	therms

	Ltwt CMU	23	78	12	41

3.5 kW). Because HVAC systems are typically oversized (the installed capacity is the required capacity rounded to the next larger available capacity), actual installed system capacity savings will be different.

LIFE CYCLE IMPACT ASSESSMENT

The second phase of a life cycle assessment, after LCI, is life cycle impact assessment. It consists of category definition, classification, and characterization. Category definition consists of identifying which impact categories are relevant for the product being studied. Classification consists of grouping related substances into impact categories. For example, the gases CO₂, methane, and N₂O contribute to climate change; so, they can be grouped together in the impact category, climate change.

According to ISO 14041, the mandatory step in life cycle impact assessment is characterization. In characterization, weighting factors are assigned according to a substance's relative contribution to the impact category. For example, the gases CO₂, methane, and N₂O contribute to climate change. In terms of global warming potential, one pound of methane is 20 times more potent than one pound of CO₂, and one pound of N₂O is 320 times more potent than one pound of CO₂. Therefore, in assessing the potential for global warming, CO₂ is assigned a weighting factor of 1, methane a factor of 20, and N₂O a factor of 320. It is important to remember that there is no scientific basis for comparing across impact categories.^[22]

According to ISO 14042, life cycle impact assessment is not intended to identify, measure or predict actual impacts or estimate threshold limits, or measure margins of safety.^[22] The methodology is still being developed, and there is no general and widespread practice of life cycle impact assessment at this time or an agreement on specific methodologies.^[22] Therefore, several of the available methods were used to measure the life cycle impact assessment. The methods chosen are Eco-Indicator 99 (Dutch/Swiss), EDIP/UMIP 96 (Danish), and EPS 2000 (Swedish). Furthermore, three different weighting sets in Eco-Indicator 99 were used.

The Eco-Indicator 99 method is a damage-oriented approach, which is based on how a panel of experts weighted the different types of damage caused by the impact categories. The three versions of Eco-Indicator 99 reflect the subjective uncertainty inherent in LCA. Each one takes a different perspective on how to consider the potential damage from a particular substance. The egalitarian perspective takes an extremely long-term look at substances if there is any indication that they have some effect. The hierarchic perspective takes a long-term look at all substances if there is consensus regarding their effect. The individualist perspective takes a short-term look (100 years or less) at substances if there is complete proof regarding their effect.

The EDIP/UMIP 96 method is based on normalizing values to person-equivalents in 1990 and weighting factors are equivalent to politically-set target-emissions per person in 2000. The EPS method was designed as a tool for a company's internal product development process, and the weighting factors are based on a willingness to pay to avoid change. A listing of the impact categories in each method is shown in Table 9. A complete description of the category definitions, classification methods, and characterization factors for each of the three methods is too voluminous to be reproduced in this report. Please refer to Appendices E through G for a summary of each method and further references.

Results of the characterization phase for each method are shown in Tables 10 through 14. The data show similar results for the two houses. In most cases the lightweight CMU house has lower (better) impact indicators in the colder climates (El Paso, Knoxville, Providence, and Detroit). In the warmest climate (Tampa), the impact indicators are generally greater for the lightweight CMU house because household energy use is also greater. The exceptions are (i) in the categories "respiratory inorganics," "land use," and "minerals" in the Eco-Indicator methods and the categories "life expectancy," "severe morbidity," "severe nuisance," and "species extinction" in the EPS 2000 method, where impact indicators for the lightweight CMU house are greater, and (ii) "radiation" and "ozone" in the Eco-Indicator methods and the categories "ozone depletion," "ecotoxicity," and "human toxicity, water" in the EDIP/UMIP 96 method, where indicators for the wood house are greater.

Other methods of impact assessment, such as damage assessment, normalization, and weighting, are optional. In damage assessment, impact categories that have equivalent units are added. In normalization, the impact assessment values are compared to some reference, such as the average yearly environmental load in a country divided by the number of people in the

Table 9. Impact Categories for Three Life Cycle Impact Assessment Methods

Eco-Indicator 99	EDIP/UMIP 96	EPS 2000
Carcinogens	Global warming potential	Life expectancy
Respiratory organics	Ozone depletion	Severe morbidity and suffering
Respiratory inorganics	Acidification	Morbidity
Climate change	Eutrophication	Severe nuisance
Radiation	Photochemical smog	Nuisance
Ozone layer	Ecotoxicity water, chronic	Crop growth capacity
Ecotoxicity	Ecotoxicity water, acute	Wood growth capacity
Acidification/eutrophication	Ecotoxicity soil, chronic	Fish and meat production
Land use	Human toxicity, air	Soil acidification
Minerals	Human toxicity, water	Production capacity of irrigation water
Fossil fuels	Human toxicity, soil	Production capacity of drinking water
	Bulk waste	Depletion of reserves
	Hazardous waste	Species extinction
	Radioactive waste	
	Slags/ashes	
	Resources (all)	

country. In weighting, the impact assessment values in several or all categories are multiplied by weighting factors and added together to get a single score. However, the weighting factors used are always subjective and reflect societal or personal values. Furthermore, according to ISO 14042, weighting cannot be used to make comparative assertions disclosed to the public.^[22] The tables in Appendix H show the normalized and weighted results for each category of each method. In each of the five methods, the lightweight CMU houses in four climates (El Paso, Knoxville, Providence, and Detroit) have a lower score than the wood frame house in almost all impact categories. A summary of the normalized and weighted single-score results is shown in Table 15. The data in Table 15 are shown graphically in the figures in Appendix I.

LIFE CYCLE INTERPRETATION

A breakdown of the LCA by major process/product stage shows that most of the environmental load is from the household-use of natural gas and electricity during the life of the houses. For example, Figures 2 and 3 show the breakdown for the lightweight CMU houses in Tampa and Detroit, respectively, using the egalitarian perspective of Eco-Indicator 99. Figures 4 and 5 show that the wood frame houses exhibit similar patterns. The breakdown for all houses in all locations is shown in Figures J-1 through J-10 in Appendix J. The household-use of electricity and natural gas represents 87% to 91% of the environmental load of the lightweight CMU houses. The household-use of electricity and natural gas represents 89% to 93% of the environmental load of the wood frame houses. Household-use of energy is less in milder climates (like Tampa) than in more severe climates (like Detroit), so the houses in milder climates are at the low end of the range, while houses in more severe climates are at the high end of the range. The household-use of electricity (mostly for cooling) contributes the most to the total environmental load in cooling-dominant climates like Tampa. Household natural gas use (mostly for heating) contributes the

	Detroit	164,000	178,000	117,000	686,000	973,000			

*No units: data have been normalized and weighted.

most to the total environmental load in heating-dominant climate like Detroit. In all locations, cement-based materials represent a small fraction of the total environmental load. Furthermore, Figures 2 through 5 also show that the most significant impact categories are fossil fuel depletion and respiratory inorganics. The other methods of life cycle impact assessment produce similar results.

When considering only the construction materials for the lightweight CMU house, most of the environmental load is from wood, with total cement-based materials second. For the wood house, most of the environmental load of construction materials is from wood and copper tubing, with total cement-based materials third. For example, Figures 6 and 7 show a breakdown of the environmental load of buildings materials for each of the houses in Detroit using the egalitarian perspective of the Eco-Indicator 99 Method. Furthermore, the impact categories that contribute the most to the environmental load are (i) land use, fossil fuel depletion, and respiratory inorganics, primarily from cement-based materials, wood, and copper tubing in the lightweight CMU house, and (ii) land use and fossil fuel depletion, primarily from wood and copper tubing in the wood house. Figures K-1 through K-10 in Appendix K show the breakdown of environmental load for all locations.

Complete disposal scenarios have not been included in this LCA. Including complete disposal scenarios (notably decomposition of wood-based products in landfill) will not significantly alter the results of this LCA.

CONCLUSIONS

This report presented the results of an LCA a house modeled with two types of exterior walls: a wood-framed wall and a lightweight CMU wall. The LCA was carried out according to the ISO 14040 series guidelines. The house was modeled in five cities, representing a range of U.S. climates: Tampa, El Paso, Knoxville, Providence, and Detroit.

Each house is a two-story single-family building with a contemporary design. The house system boundary includes the inputs and outputs of energy and material from construction,

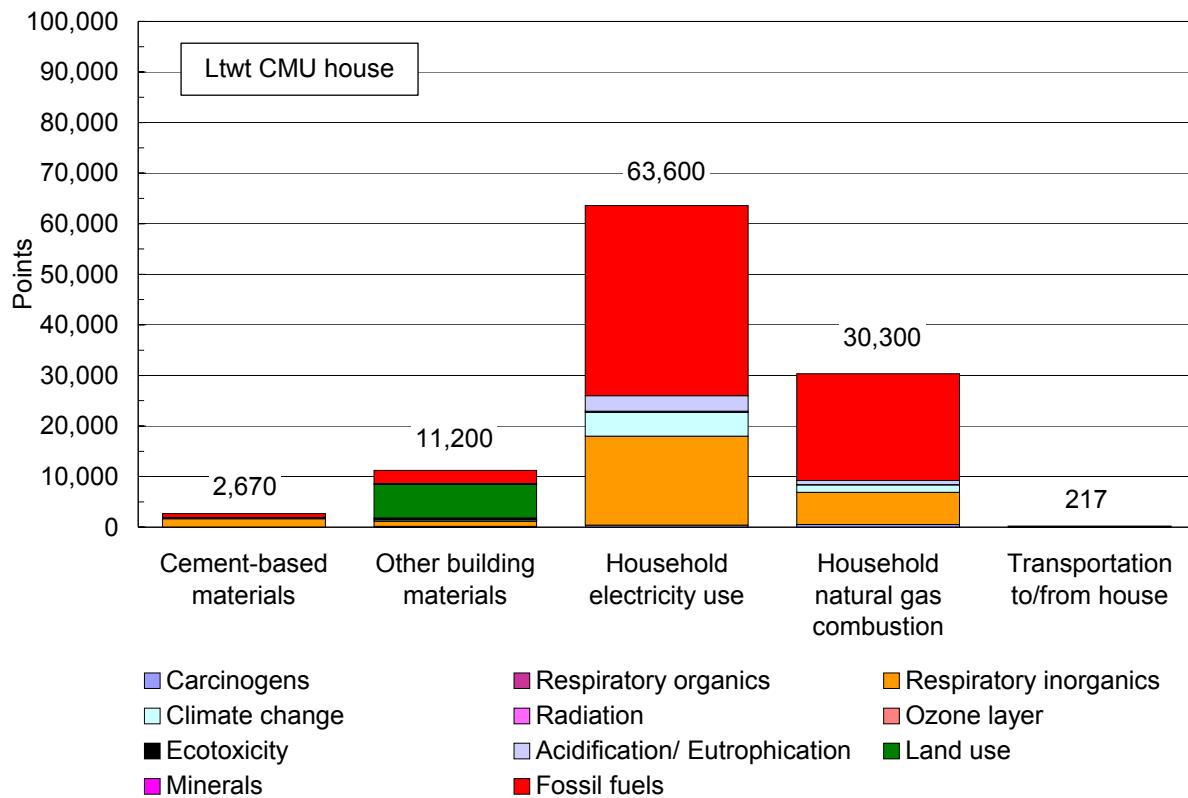

Figure 2. Single-score life cycle inventory assessment of lightweight CMU house in Tampa showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

occupancy and maintenance. The system boundary excludes human resources, infrastructure, accidental spills, impacts caused by people, and decomposition of household components after disposal. The life of the houses is 100 years.

The LCA was conducted by first assembling the relevant LCI data from published reports and commercially available databases. The LCA software tool, SimaPro, was used to perform a life cycle impact assessment. Impact assessment is not completely scientific; so three different models were used. The methods chosen are Eco-Indicator 99 (Dutch/Swiss), EDIP/UMIP 96 (Danish), and EPS 2000 (Swedish). Furthermore, three different weighting sets in Eco-Indicator 99 were used.

The data show similar results for the two houses. In most cases the lightweight CMU house has lower (better) impact indicators in the colder climates (El Paso, Knoxville, Providence, and Detroit). In the warmest climate (Tampa), the impact indicators are generally greater for the lightweight CMU house because household energy use is also greater. The exceptions are (i) in the categories “respiratory inorganics,” “land use,” and “minerals” in the Eco-Indicator methods and the categories “life expectancy,” “severe morbidity” “severe nuisance,” and “species extinction” in the EPS 2000 method, where impact indicators for the lightweight CMU house are greater, and (ii) “radiation” and “ozone” in the Eco-Indicator methods and the categories “ozone depletion,” “ecotoxicity,” and “human toxicity, water” in the EDIP/UMIP 96 method, where indicators for the wood house are greater.

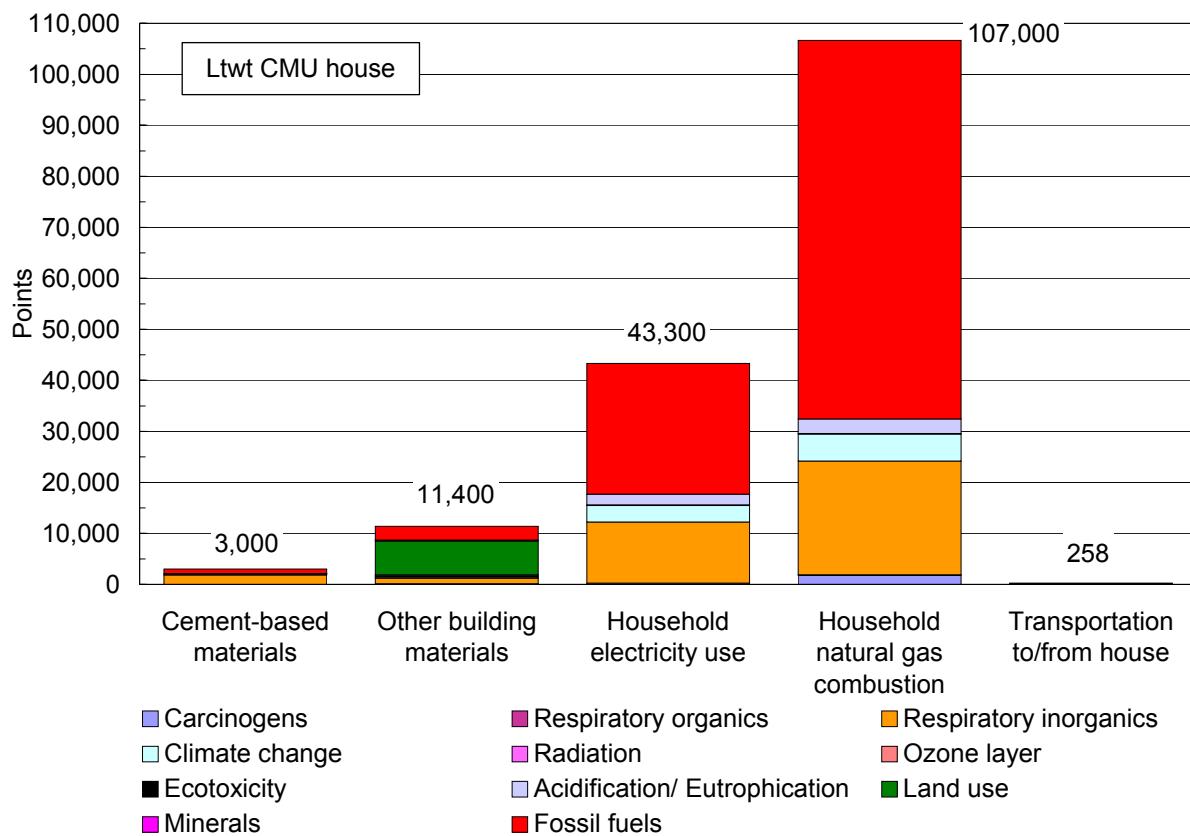

Figure 3. Single-score life cycle inventory assessment of lightweight CMU house in Detroit showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

The most significant environmental impacts are not from the construction materials but from the production and use of electricity and natural gas in the houses by the occupants. Furthermore, the largest impacts from these uses are in the form of depletion of fossil fuel reserves (categorized as damage to natural resources) and release to the air of respiratory inorganics (categorized as damage to human health).

When considering only the construction materials for the lightweight CMU house, most of the environmental load is from wood, with total cement-based materials second. For the wood house, most of the environmental load of construction materials is from wood and copper tubing, with total cement-based materials third.

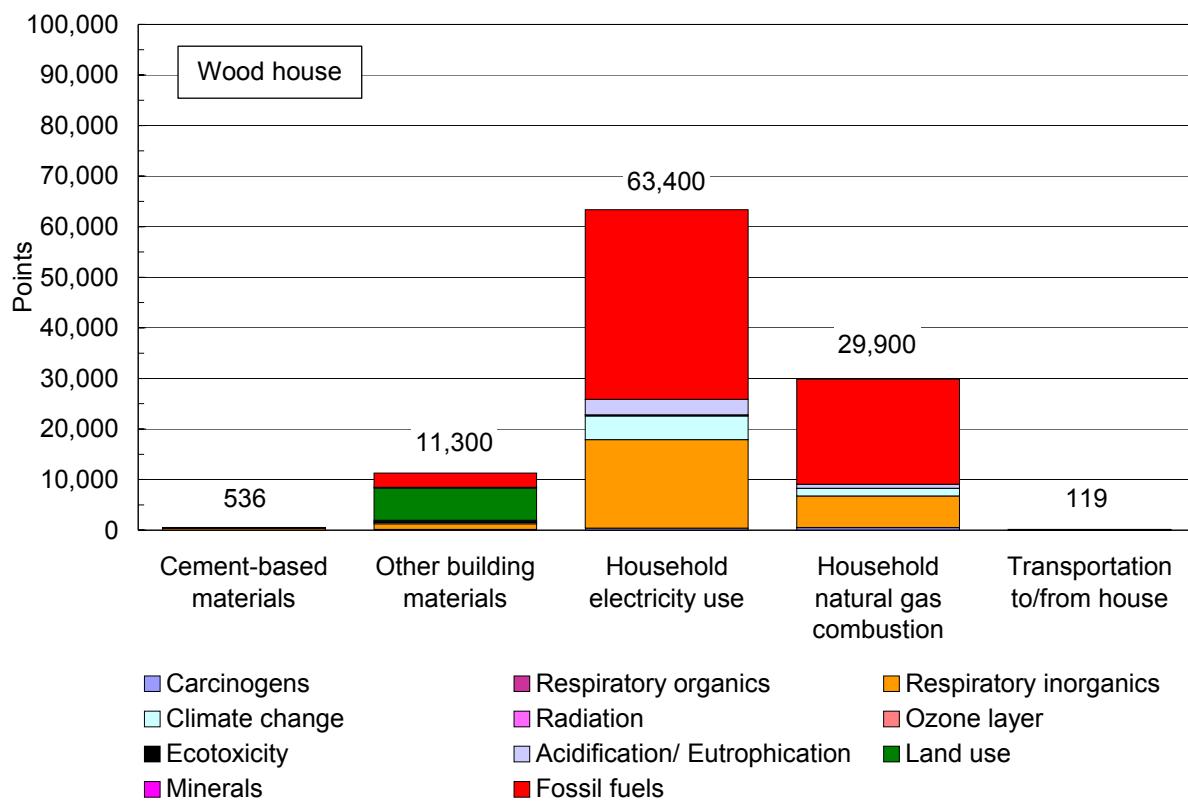

Figure 4. Single-score life cycle inventory assessment of wood frame house in Tampa showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

APPENDIX A – TARGET AUDIENCES AND INFORMATION TO BE COMMUNICATED

This report is one of many for the Environmental Life Cycle Assessment (LCA) of Portland Cement Concrete project sponsored by the Portland Cement Association.

The objectives of publishing reports and disseminating information are to:

- Determine the environmental life cycle benefits associated with the use of these products.
- Produce comparisons of concrete and other building materials.
- Provide information about these benefits to manufacturers and users of these products.
- Provide life cycle inventory (LCI) and LCA information to practitioners and others, such as data base providers in need of accurate data on cement and concrete.

The contents of the reports will provide information for the following audiences:

- Members of the Portland Cement Association (PCA) and other organizations that promote the use of cement and concrete, generally called “allied industries.”
- Members of the Environmental Council of Concrete Organizations (ECCO).
- LCA practitioners and database developers.
- Engineers, architects, and designers.
- Public agencies (Departments of Transportation [DOTs], Energy Star, Environmentally Preferable Purchasing Program).
- General public.

The report formats are not particularly suited for all audiences. The reports are intended to document the particular partial LCI, LCI, or LCA. They provide data in a transparent, traceable format for documentation purposes. The intent is that abbreviated papers, brochures, data packages, presentations, or press releases can be developed from the project reports. The materials presenting the results of this project will be matched, in form and format, to the needs of the target audience. The materials have been categorized as follows:

- General Information:
 - Purpose of life cycle assessments (LCAs) and how they are done.
 - Limited life cycle results of portland cement concrete products from production through use to demolition and recycling.
- Summary Results:
 - Presentation of selected life cycle inventory (LCI) data in the form of summary information, bar charts or other diagrams; for example PowerPoint™ presentations.
 - Published papers or articles.
- Detailed Results:
 - LCI results for databases or LCA models, such as BEES or Athena.
 - Description of the LCI methodology used in the project and specific assumptions, information sources/references, and detailed results.

**APPENDIX C – LCI DATA FOR WOOD HOUSES AND LIGHTWEIGHT
CMU HOUSES – SI UNITS**

SIMAPRO: A LIFE CYCLE ASSESSMENT TOOL

The Dutch company PRé Consultants is a leader in developing tools for life cycle assessment. They created and continue to develop SimaPro, the most widely used life cycle assessment tool (www.pre.nl/simapro). SimaPro can be used to perform detailed and robust life cycle assessments of materials, components, buildings, and processes. It contains a large database of products and processes and seven comprehensive, widely-accepted impact assessment methods.

The user can either build up a product or process from scratch using the databases supplied with SimaPro, or the LCI of an existing product or process can be augmented with upstream and downstream profiles for other processes to determine a life cycle assessment. The impact assessment methods can be utilized to determine the impacts of materials, energy use, and pollutants. For example, upstream profiles can be the energy sources or extraction of raw materials. Downstream profiles can be other manufacturing steps used to make a final product.

**APPENDIX D – LCI DATA FOR WOOD HOUSES AND LIGHTWEIGHT
CMU HOUSES – U.S. CUSTOMARY UNITS**

SIMAPRO: A LIFE CYCLE ASSESSMENT TOOL

The Dutch company PRé Consultants is a leader in developing tools for life cycle assessment. They created and continue to develop SimaPro, the most widely used life cycle assessment tool (www.pre.nl/simapro). SimaPro can be used to perform detailed and robust life cycle assessments of materials, components, buildings, and processes. It contains a large database of products and processes and seven comprehensive, widely-accepted impact assessment methods.

The user can either build up a product or process from scratch using the databases supplied with SimaPro, or the LCI of an existing product or process can be augmented with upstream and downstream profiles for other processes to determine a life cycle assessment. The impact assessment methods can be utilized to determine the impacts of materials, energy use, and pollutants. For example, upstream profiles can be the energy sources or extraction of raw materials. Downstream profiles can be other manufacturing steps used to make a final product.

APPENDIX E – THE ECO-INDICATOR IMPACT ASSESSMENT METHOD
(used with permission)

2.4 Eco-indicator 99

2.4.1 Introduction

Eco-indicator 99 is the successor of Eco-indicator 95. Both methods use the damage-oriented approach. The development of the Eco-indicator 99 methodology started with the design of the weighting procedure. Traditionally in LCA the emissions and resource extractions are expressed as 10 or more different impact categories, like acidification, ozone layer depletion, ecotoxicity and resource extraction. For a panel of experts or non-experts it is very difficult to give meaningful weighting factors for such a large number and rather abstract impact categories. It was concluded that the panel should not be asked to weight the impact categories but the different types of damage that are caused by these impact categories. The other improvement was to limit the number of items that are to be assessed. As a result the panel, consisting of 365 persons from a Swiss LCA interest group, was asked to assess the seriousness of three damage categories:

1. Damage to Human Health, expressed as the number of year life lost and the number of years lived disabled. These are combined as Disability Adjusted Life Years (DALYs), an index that is also used by the Worldbank and WHO.
2. Damage to Ecosystem Quality, express as the loss of species over an certain area, during a certain time
3. Damage to Resources, expressed as the surplus energy needed for future extractions of minerals and fossil fuels.

In order to be able to use the weights for the three damage categories a series of complex damage models had to be developed. In figure 2 these models are represented in a schematic way.

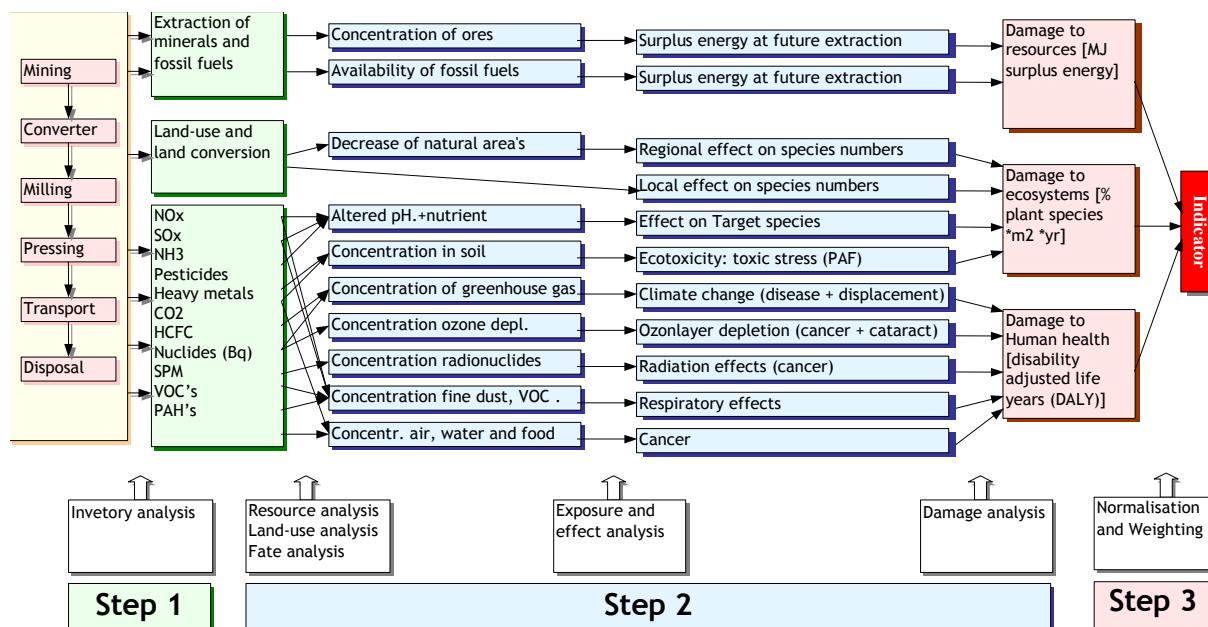

Figure 1: Detailed representation of the damage model

In general, the factors used in SimaPro do not deviate from the ones in the (updated) report. In case the report contained synonyms of substance names already available in the substance list of the SimaPro database, the existing names in the database are used. A distinction is made for emissions to agricultural soil and industrial soil, indicated with respectively (agr.) or (ind.) behind substance names emitted to soil.

2.4.2 Characterisation

Emissions

Characterisation factors are calculated at end-point level (damage). The damage model for emissions includes fate analysis, exposure, effects analysis and damage analysis.

This model is applied for the following impact categories:

- **Carcinogens**
Carcinogenic affects due to emissions of carcinogenic substances to air water and soil. Damage is expressed in Disability adjusted Life Years (DALY) / kg emission.
- **Respiratory organics**
Respiratory effects resulting from summer smog, due to emissions of organic substances to air, causing respiratory effects. Damage is expressed in Disability adjusted Life Years (DALY) / kg emission.
- **Respiratory inorganics**
Respiratory effects resulting from winter smog caused by emissions of dust, sulphur and nitrogen oxides to air. Damage is expressed in Disability adjusted Life Years (DALY) / kg emission.
- **Climate change**
Damage, expressed in DALY/kg emission, resulting from an increase of diseases and death caused by climate change.
- **Radiation**
Damage, expressed in DALY/kg emission, resulting from radioactive radiation
- **Ozone layer**
Damage, expressed in DALY/kg emission, due to increased UV radiation as a result of emission of ozone depleting substances to air.
- **Ecotoxicity**
Damage to ecosystem quality, as a result of emission of ecotoxic substances to air, water and soil. Damage is expressed in Potentially Affected Fraction (PAF)*m²*year/kg emission.
- **Acidification/ Eutrophication**
Damage to ecosystem quality, as a result of emission of acidifying substances to air. Damage is expressed in Potentially Disappeared Fraction (PDF)*m²*year/kg emission.

Land use

Land use (in man made systems) has impact on species diversity. Based on field observations, a scale is developed expressing species diversity per type of land use. Species diversity depends on the type of land use and the size of the area. Both regional effects and local effects are taken into account in the impact category:

- **Land use**
Damage as a result of either conversion of land or occupation of land. Damage is expressed in Potentially Disappeared Fraction (PDF)*m²*year/m² or m²a.

Resource depletion

Mankind will always extracts the best resources first, leaving the lower quality resources for future extraction. The damage of resources will be experienced by future generations, as they will have to use more effort to extract remaining resources. This extra effort is expressed as “surplus energy”.

- **Minerals**
Surplus energy per kg mineral or ore, as a result of decreasing ore grades.
- **Fossil fuels**
Surplus energy per extracted MJ, kg or m³ fossil fuel, as a result of lower quality resources.

2.4.3 Uncertainties

Of course it is very important to pay attention to the uncertainties in the methodology that is used to calculate the indicators. Two types are distinguished:

1. Uncertainties about the correctness of the models used
2. Data uncertainties

Data uncertainties are specified for most damage factors as squared geometric standard deviation in the original reports, but not in the method in SimaPro. It is not useful to express the uncertainties of the model as a distribution. Uncertainties about the model are related to subjective choices in the model. In order to deal with them we developed three different versions of the methodology, using the archetypes specified in Cultural Theory. The three versions of Eco-indicator 99 are:

1. the egalitarian perspective
2. the hierarchist perspective
3. the individualist perspective

Hierarchist perspective

In the hierarchist perspective the chosen time perspective is long-term, substances are included if there is consensus regarding their effect. For instance all carcinogenic substances in IARC class 1, 2a and 2b are included, while class 3 has deliberately been excluded. In the hierarchist perspective damages are assumed to be avoidable by good management. For instance the danger people have to flee from rising water levels is not included. In the case of fossil fuels the assumption is made that fossil fuels cannot easily be substituted. Oil and gas are to be replaced by shale, while coal is replaced by brown coal. In the DALY calculations age weighting is not included.

Egalitarian perspective

In the egalitarian perspective the chosen time perspective is extremely long-term, Substances are included if there is just an indication regarding their effect. For instance all carcinogenic substances in IARC class 1, 2a, 2b and 3 are included, as far as information was available. In the egalitarian perspective, damages cannot be avoided and may lead to catastrophic events. In the case of fossil fuels the assumption is made that fossil fuels cannot be substituted. Oil, coal and gas are to be replaced by a future mix of brown coal and shale. In the DALY calculations age weighting is not included.

Individualist perspective

In the individualist perspective the chosen time perspective is short-term (100 years or less). Substances are included if there is complete proof regarding their effect. For instance only carcinogenic substances in IARC class 1 included, while class 2a, 2b and 3 have deliberately been excluded. In the individualist perspective damages are assumed to be recoverable by technological and economic development. In the case of fossil fuels the assumption is made that fossil fuels cannot really be depleted. Therefore they are left out. In the DALY calculations age weighting is included.

Damage assessment

Damages of the impact categories result in three types of damages:

1. Damage to **Human Health**, expressed as the number of year life lost and the number of years lived disabled. These are combined as Disability Adjusted Life Years (DALYs), an index that is also used by the World bank and the WHO.
2. Damage to **Ecosystem Quality**, express as the loss of species over an certain area, during a certain time
3. Damage to **Resources**, expressed as the surplus energy needed for future extractions of minerals and fossil fuels.

2.4.4 Normalisation

Normalisation is performed on damage category level. Normalisation data is calculated on European level, mostly based on 1993 as base years, with some updates for the most important emissions.

2.4.5 Weighting

In this method weighting is performed at damage category level (endpoint level in ISO). A panel performed weighting of the three damage categories. For each perspective, a specific weighting set is available. The average result of the panel assessment is available as weighting set.

2.4.6 Default

The hierarchist version of Eco-indicator 99 with average weighting is chosen default. In general value choices made in the hierarchist version are scientifically and politically accepted.

APPENDIX F – THE EDIP/UMIP 96 IMPACT ASSESSMENT METHOD
(used with permission)

2.7 EDIP/UMIP 96

2.7.1 Introduction

The EDIP method (Environmental Design of Industrial Products, in Danish UMIP) was developed in 1996. Excluded in this version of the method in SimaPro are working environment and emissions to waste water treatment plants (WWTP). An update of the method is expected by the beginning of 2002.

2.7.2 Characterisation

Global warming is based on the IPCC 1994 Status report. Is SimaPro GWP 100 is used. Stratospheric ozone depletion potentials are based on the status reports (1992/1995) of the Global Ozone Research Project (infinite time period used in SimaPro). Photochemical ozone creation potentials (POCP) were taken from UNECE reports (1990/1992). POCP values depend on the background concentration of NO_x, in SimaPro we have chosen to use the POCPs for high background concentrations. Acidification is based on the number of hydrogen ions (H⁺) that can be released. Eutrophication potential is based on N and P content in organisms. Waste streams are divided in 4 categories, bulk waste (not hazardous), hazardous waste, radioactive waste and slags and ashes. All wastes are reported on a mass basis.

Ecotoxicity is based on a chemical hazard screening method, which looks at toxicity, persistency and bioconcentration. Fate or the distribution of substances into various environmental compartments is also taken account. Ecotoxicity potentials are calculated for acute and chronic ecotoxicity to water and chronic ecotoxicity for soil. As fate is included, an emission to water may lead not only to chronic and acute ecotoxicity for water, but also to soil. Similarly an emission to air gives ecotoxicity for water and soil. This is the reason you will find emissions to various compartments in each ecotoxicity category.

Human toxicity is based on a chemical hazard screening method, which looks at toxicity, persistency and bioconcentration. Fate or the distribution of substances into various environmental compartments is also taken account. Human toxicity potentials are calculated for exposure via air, soil, and surface water. As fate is included, an emission to water may lead not only to toxicity via water, but also via soil. Similarly an emission to air gives human toxicity via water and soil. This is the reason you will find emissions to various compartments in each human toxicity category.

Resources

As resources use a different method of weighting, it cannot be compared with the other impact categories, for which reason the weighting factor is set at zero. Resources should be handled with great care when analysing results, the characterisation and normalisation results cannot be compared with the other impact categories.

To give the user some information in a useful way all resources have been added into one impact category. As equivalency factor the result of the individual normalisation and weighting scores have been used, i.e. the resulting score per kg if they would have been calculated individually.

For detailed information on resources, including normalisation and weighting, choose the "EDIP/UMIP resources only" method.

EDIP/UMIP resources only

In the "EDIP/UMIP resources only" method only resources are reported. Opposite to the default EDIP/UMIP method, resources are given in individual impact categories, on a mass basis of the pure resource (i.e. 100% metal in ore, rather than ore). Normalisation is based on global production per world citizen, derived from World Resources 1992. Weighting of non-renewables is based on the supply-horizon (World Reserves Life Index), which specifies the period for which known reserves will last at current rates of consumption. If no normalisation data are known for an individual impact category, the normalisation value is set at one and the calculation of the weighting factor is adjusted so that the final result is still consistent. However this may give strange looking graphs in the normalisation step.

2.7.3 Normalisation

The normalisation value is based on person equivalents for 1990. For resources, normalisation and weighing are already included in the characterisation factor and therefore set at zero.

2.7.4 Weighting

The weighting factors are set to the politically set target emissions per person in the year 2000, the weighted result are expressed except for resources which is based on the proven reserves per person in 1990. For resources, normalisation and weighing are already included in the characterisation factor and therefore set at zero.

A note on weighting:

Presenting the EDIP method as a single score (addition) is allowed, however it is not recommended by the authors. Note that due to a different weighting method for resources (based on reserves rather than political targets), resources may never be included in a single score. This is the reason that the weighting factor for resources is set at zero.

APPENDIX G – THE EPS 2000 IMPACT ASSESSMENT METHOD
(used with permission)

2.6 EPS 2000 default

2.6.1 Introduction

The EPS 2000 default methodology (Environmental Priority Strategies in product design) is a damage oriented method. In the EPS system willingness to pay to restore changes in the safe guard subjects is chosen as the monetary measure. The indicator unit is ELU (Environmental Load Unit). This method includes characterisation and weighting. Normalisation is not applied.

The top-down development of the EPS system has led to an outspoken hierarchy among its principles and rules. The general principles of its development are:

- The top-down principle (highest priority is given to the usefulness of the system);
- The index principle (ready made indices represent weighted and aggregated impacts)
- The default principle (an operative method as default is required)
- The uncertainty principle (uncertainty of input data has to be estimated)
- Choice of default data and models to determine them

The EPS system is mainly aimed to be a tool for a company's internal product development process. The system is developed to assist designers and product developers in finding which one of two product concepts has the least impact on the environment. The models and data in EPS are intended to improve environmental performance of products. The choice and design of the models and data are made from an anticipated utility perspective of a product developer. They are, for instance not intended to be used as a basis for environmental protection strategies for single substances, or as a sole basis for environmental product declarations. In most of those cases additional site-specific information and modelling is necessary.

The EPS 2000 default method is an update of the 1996 version. The impact categories are identified from five safe guard subjects: human health, ecosystem production capacity, abiotic stock resource, biodiversity and cultural and recreational values.

2.6.2 Classification

Emissions and resources are assigned to impact categories when actual effects are likely to occur in the environment, based on likely exposure.

2.6.3 Characterisation

Empirical, equivalency and mechanistic models are used to calculate default characterisation values.

Human Health

In EPS weighting factors for damage to human health are included for the following indicators:

- Life expectancy, expressed in Years of life lost (person year)
- Severe morbidity and suffering, in person year, including starvation
- Morbidity, in person year, like cold or flue
- Severe nuisance, in person year, which would normally cause a reaction to avoid the nuisance
- Nuisance, in person year, irritating, but not causing any direct action

Ecosystem production capacity

The default impact categories of production capacity of ecosystems are:

- Crop production capacity, in kg weight at harvest
- Wood production capacity, in kg dry weight
- Fish and meat production capacity, in kg full weight of animals
- Base cat-ion capacity, in H⁺ mole equivalents (used only when models including the other indicators are not available)

- Production capacity of (irrigation) water, in kg which is acceptable for irrigation, with respect to persistent toxic substances
- Production capacity of (drinking) water, in kg of water fulfilling WHO criteria on drinking water.

Abiotic stock resources

Abiotic stock resource indicators are depletion of elemental or mineral reserves and depletion of fossil reserves. Some classification factors are defined 0 (zero).

In SimaPro characterisation values for abiotic depletion result from both the impact of depletion and impacts due to extraction of the element/mineral or resource.

Biodiversity

Default impact category for biodiversity is extinction of species, expressed in Normalised Extinction of species (NEX).

Cultural and recreational values

Changes in cultural and recreational values are difficult to describe by general indicators as they are highly specific and qualitative in nature. Indicators should be defined when needed, and thus are not included in the default methodology in SimaPro.

2.6.4 Weighting

In the EPS default method, weighting is made through valuation. Weighting factors represent the willingness to pay to avoid changes. The environmental reference is the present state of the environment. The indicator unit is ELU (Environmental Load Unit).

APPENDIX I – GRAPHICAL PRESENTATION OF LCA SINGLE-SCORE SUMMARY

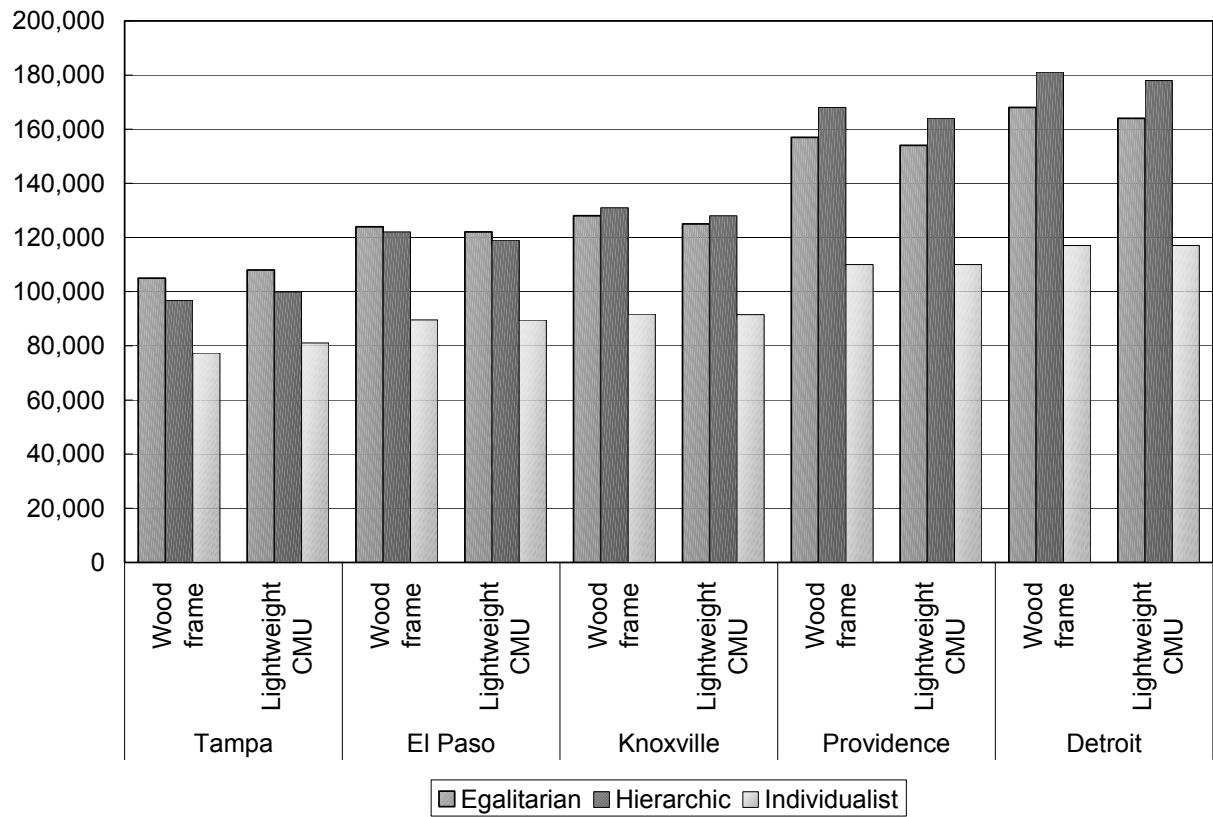

Figure I-1. LCA single score summary using the Eco-Indicator 99 method of impact assessment (there are no units because the data have been weighted and normalized).

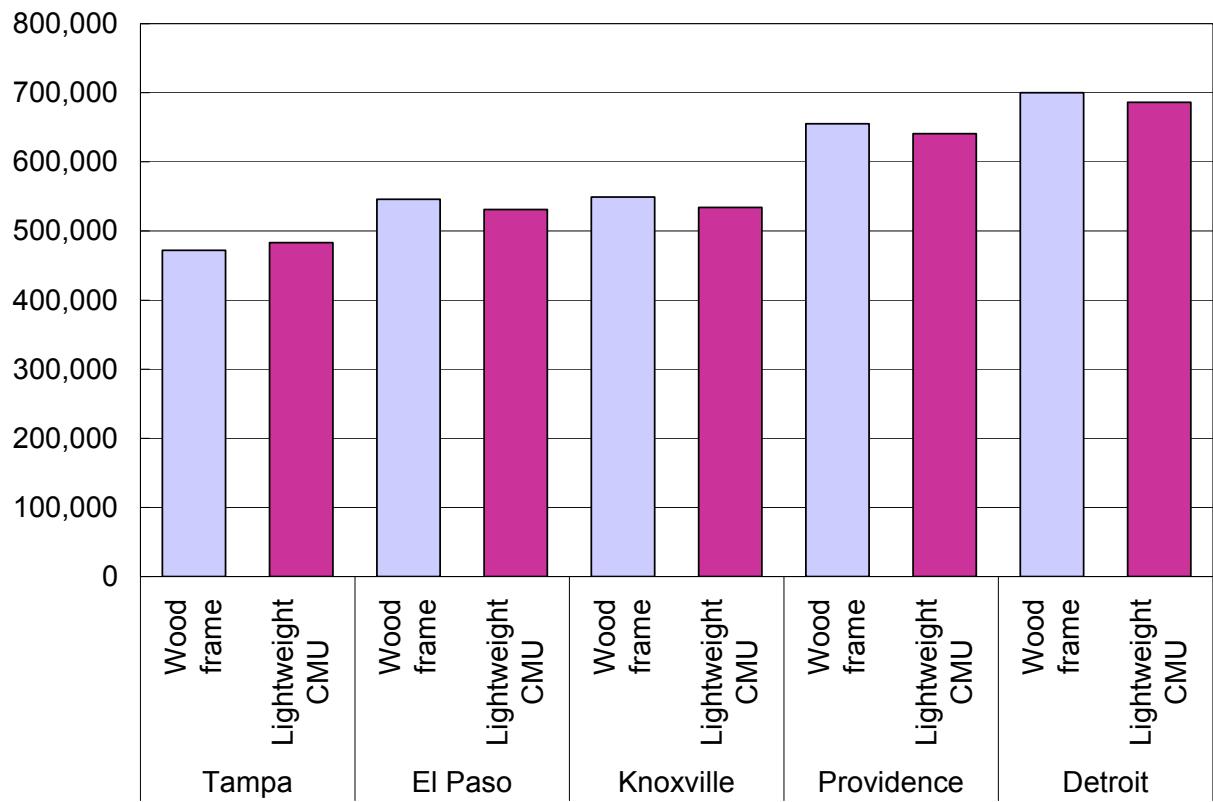

Figure I-2. LCA single score summary using the EDIP/UMIP 96 method of impact assessment (there are no units because the data have been weighted and normalized).

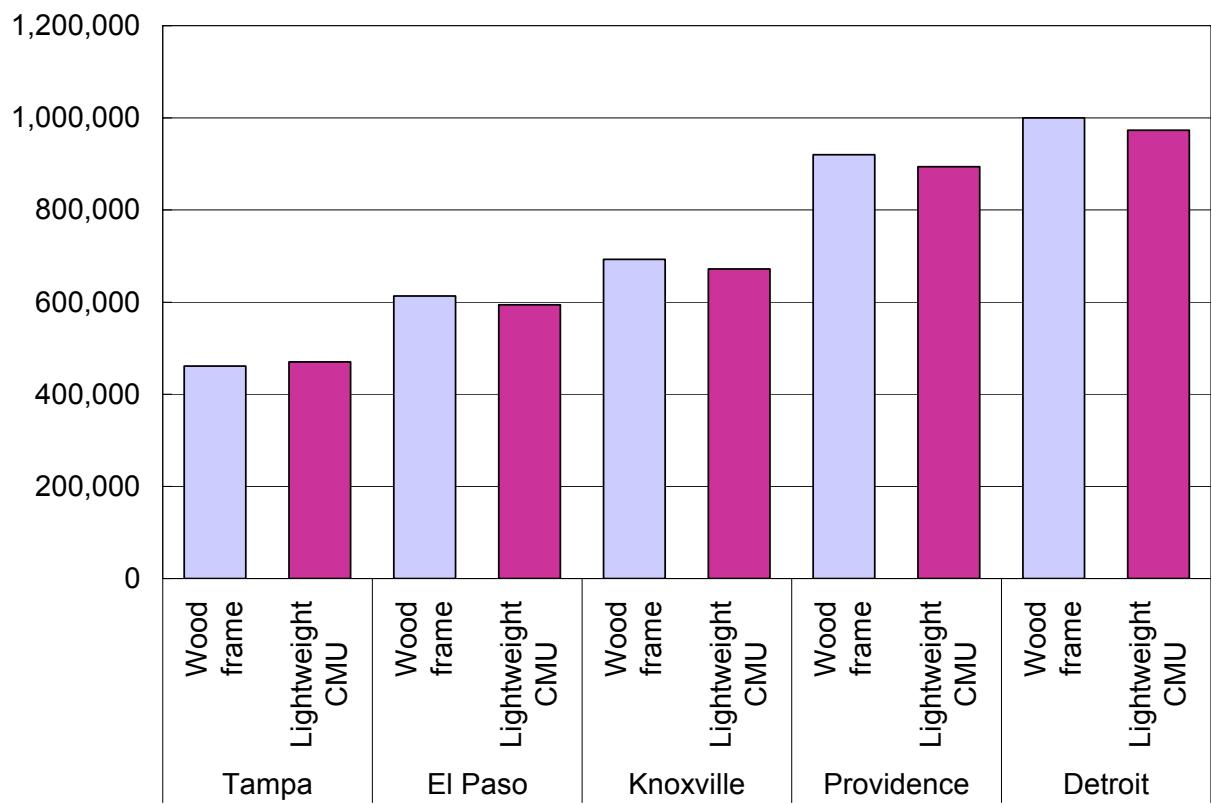

Figure I-3. LCA single score summary using the EPS 2000 method of impact assessment (there are no units because the data have been weighted and normalized).

APPENDIX J – LCA SINGLE-SCORE SUMMARY
(Output from SimaPro)

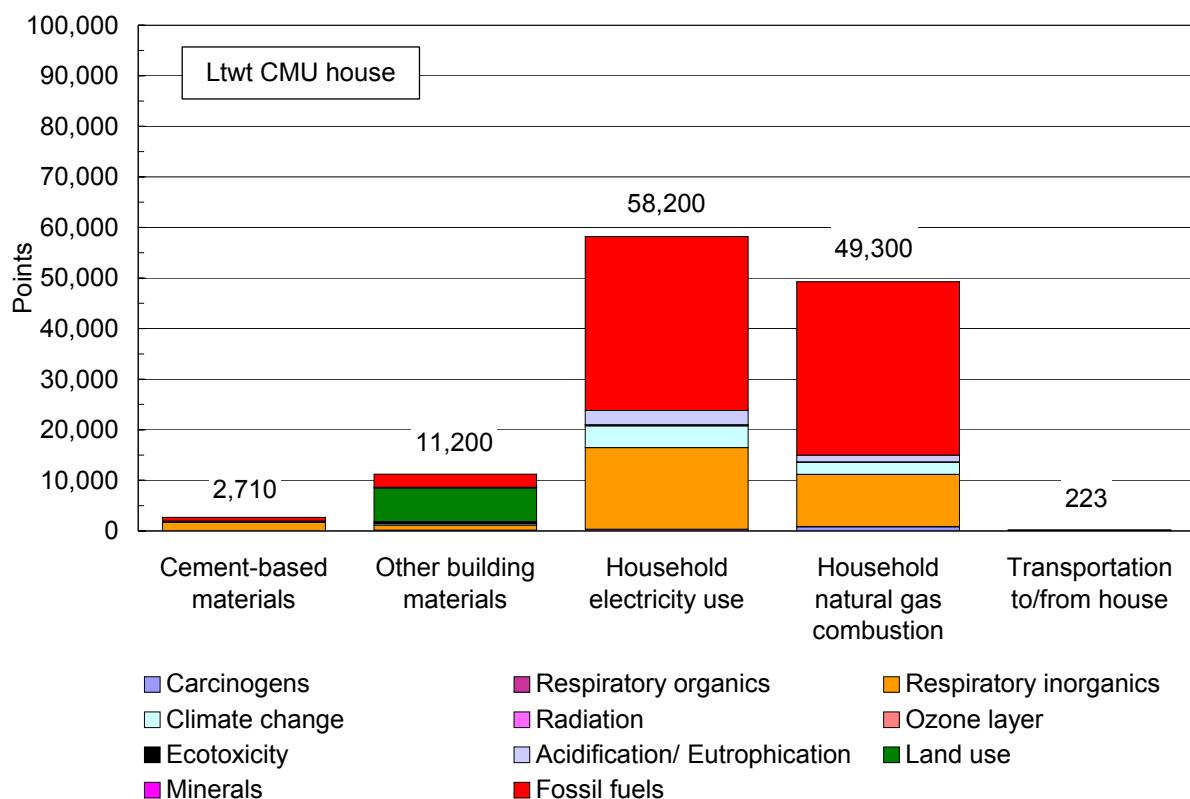

Figure J-1. Single-score life cycle inventory assessment of lightweight CMU house in El Paso showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

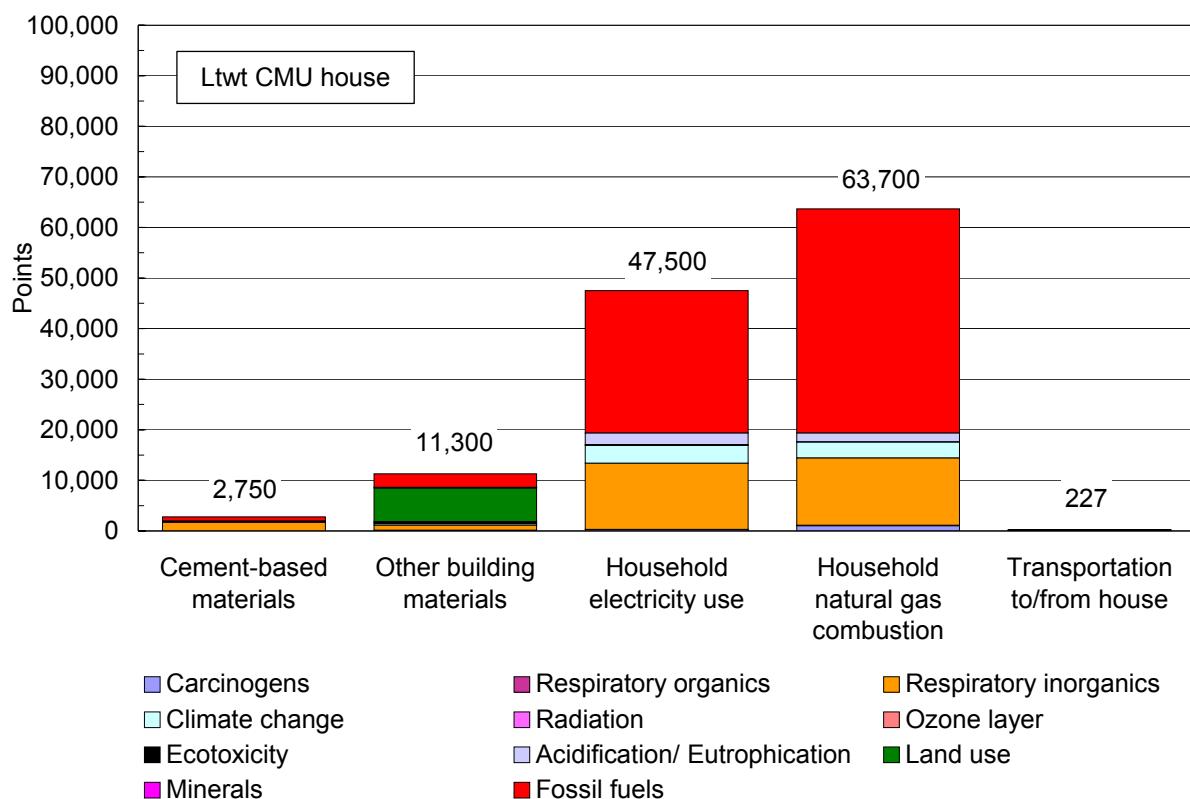

Figure J-2. Single-score life cycle inventory assessment of lightweight CMU house in Knoxville showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

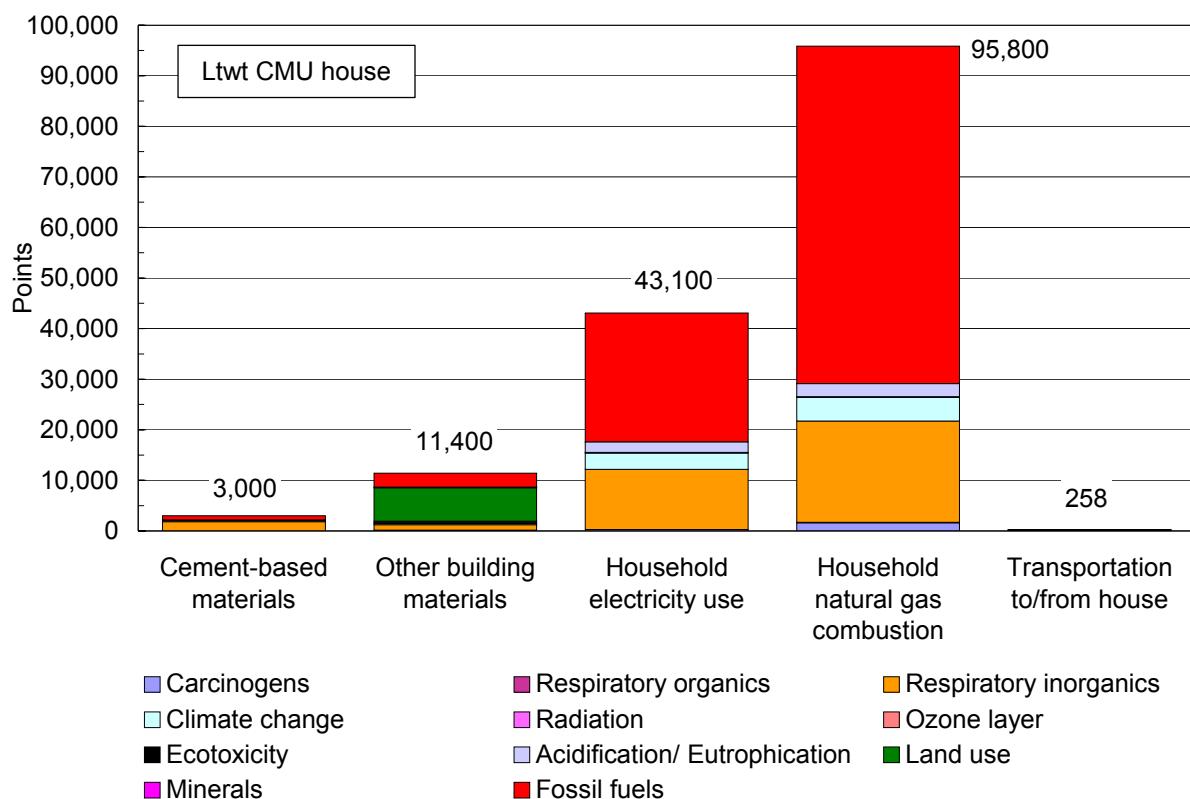

Figure J-3. Single-score life cycle inventory assessment of lightweight CMU house in Providence, showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

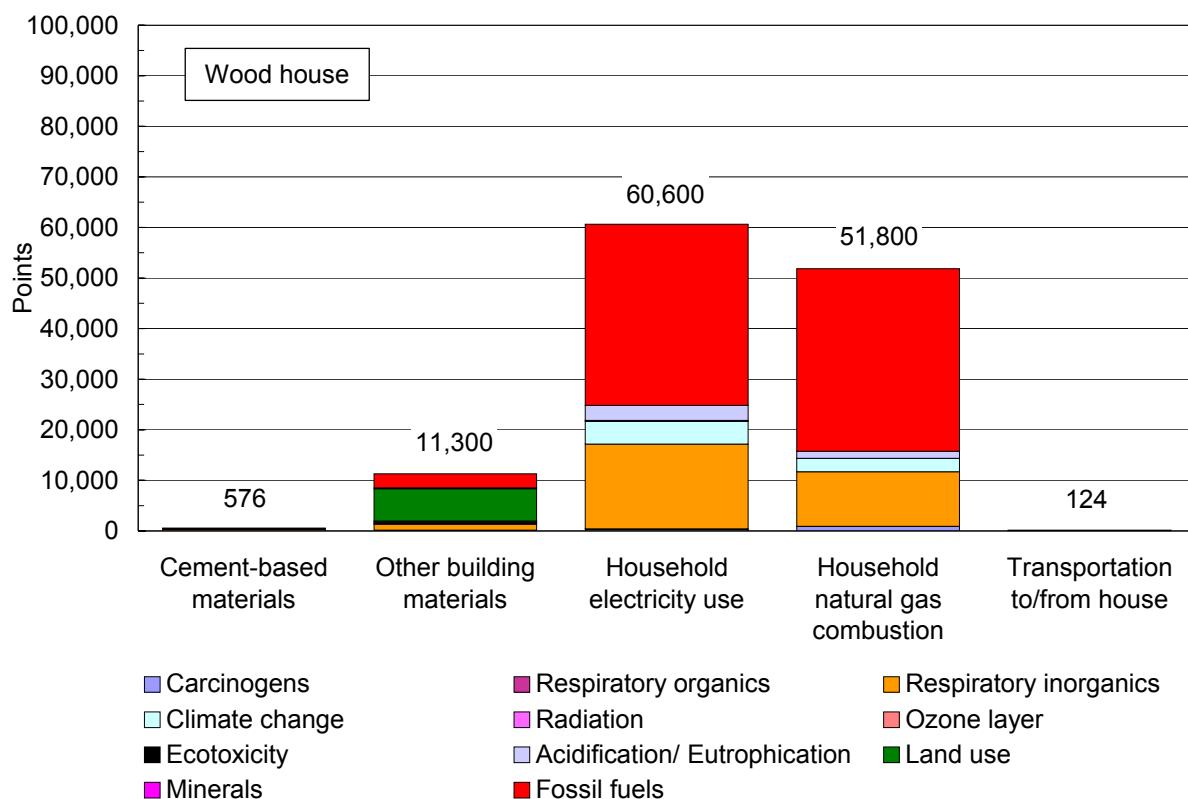

Figure J-4. Single-score life cycle inventory assessment of wood house in El Paso showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

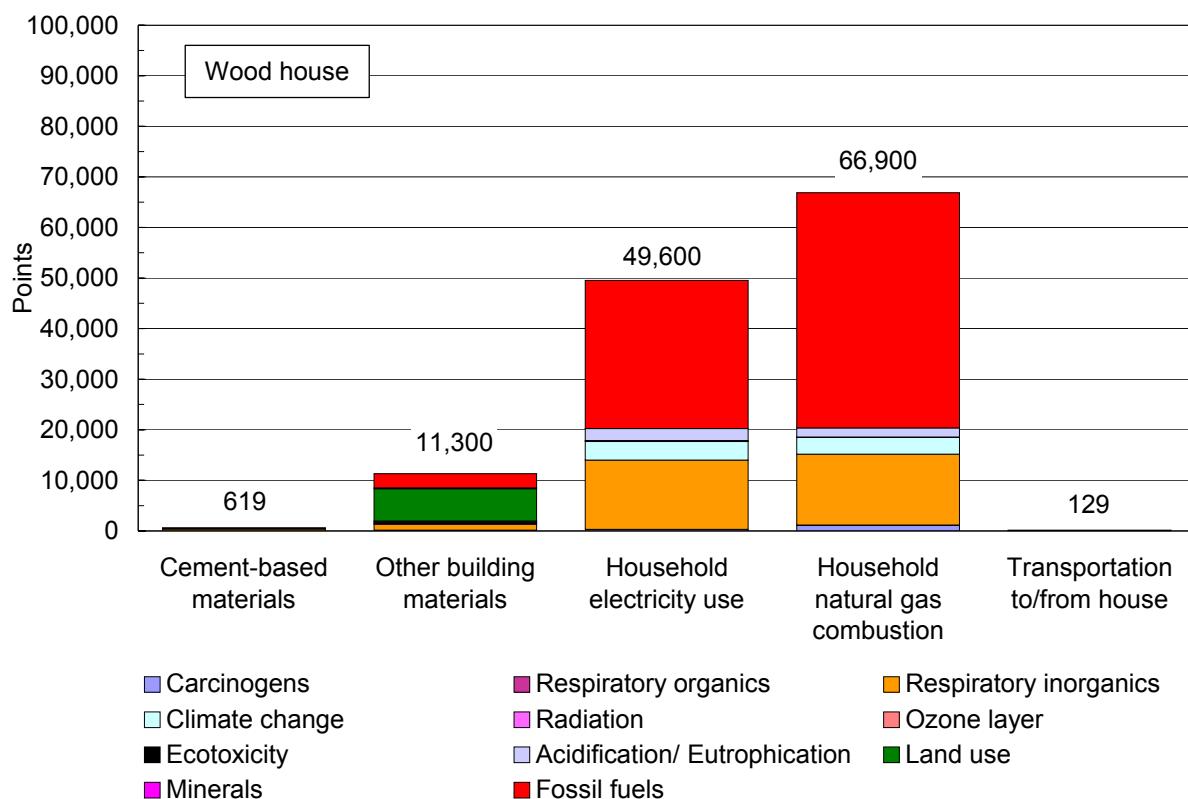

Figure J-5. Single-score life cycle inventory assessment of wood house in Knoxville showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

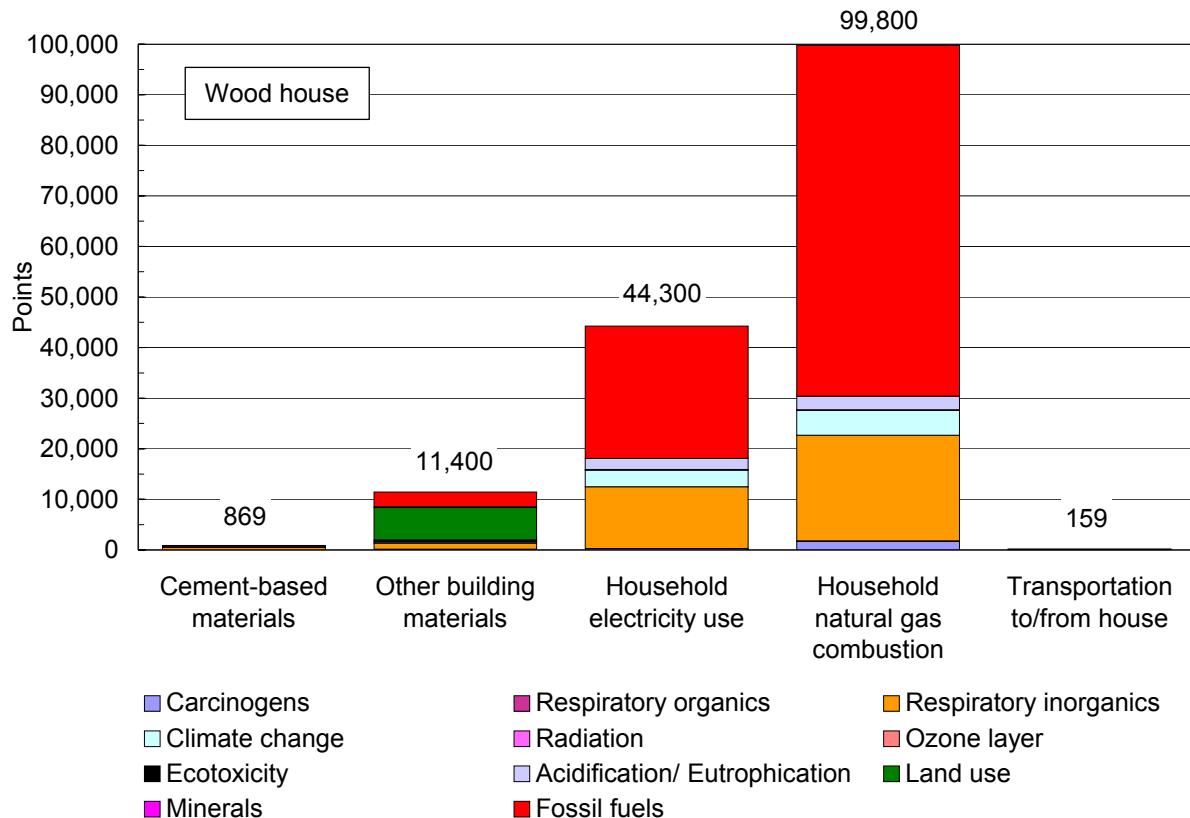

Figure J-6. Single-score life cycle inventory assessment of wood house in Providence, showing contribution of each major process/product stage (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

**APPENDIX K – BREAKDOWN OF SINGLE-SCORE LCA OF
BUILDING MATERIALS
(Output from SimaPro)**

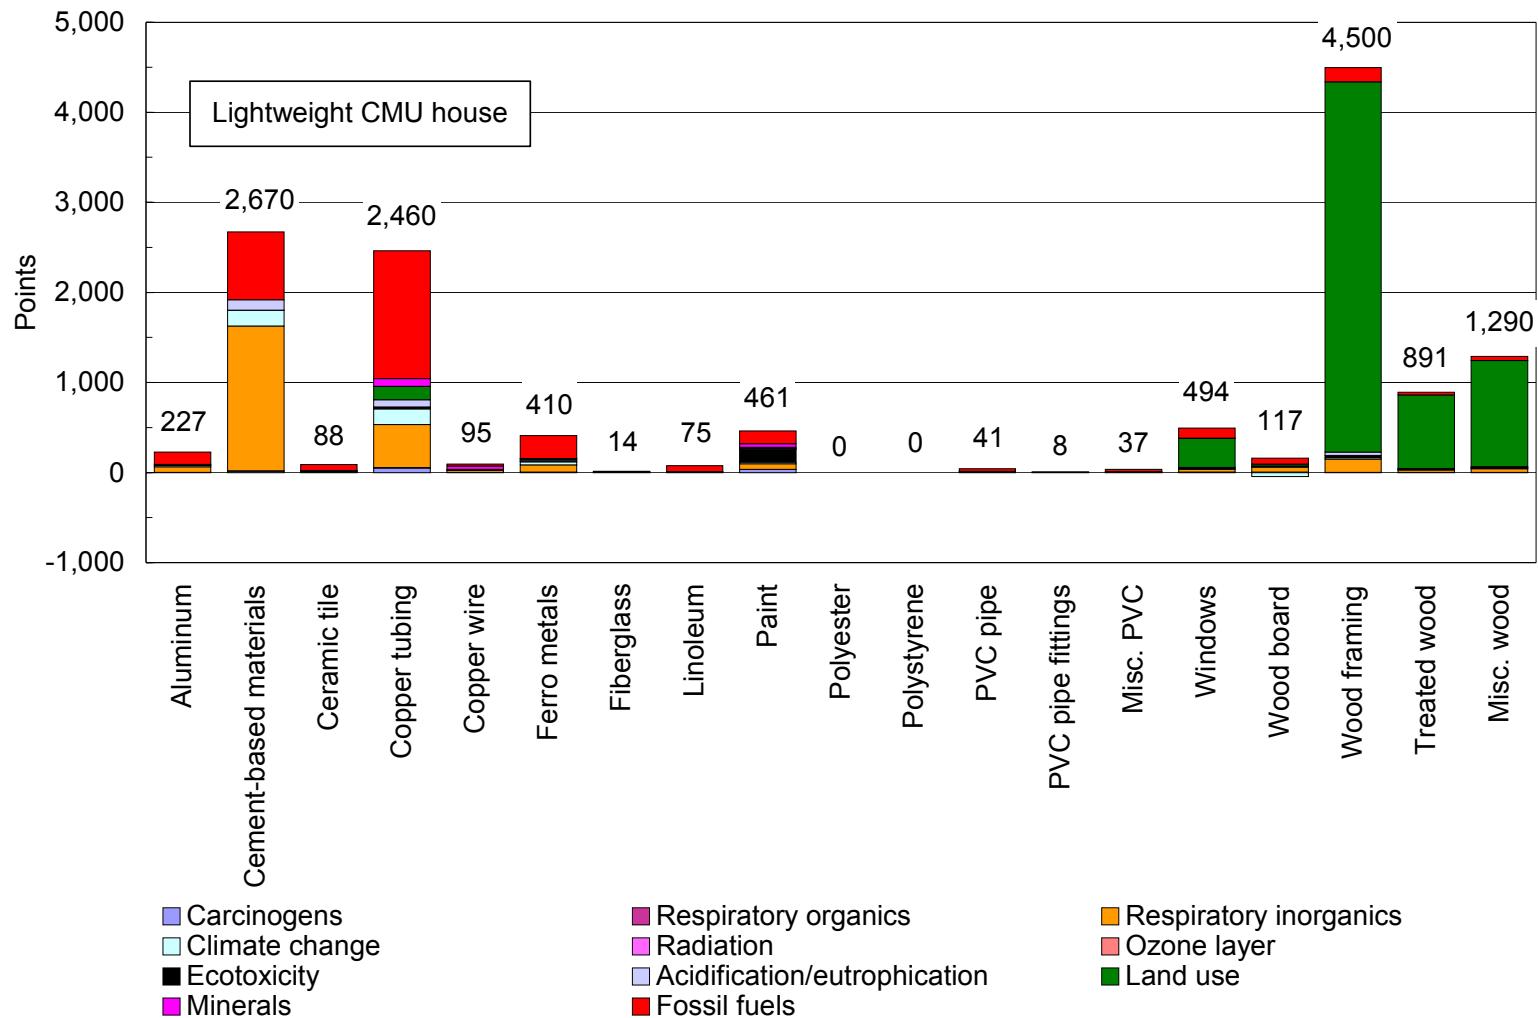

Figure K-1. Single-score life cycle inventory assessment for construction materials in the lightweight CMU house in Tampa (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

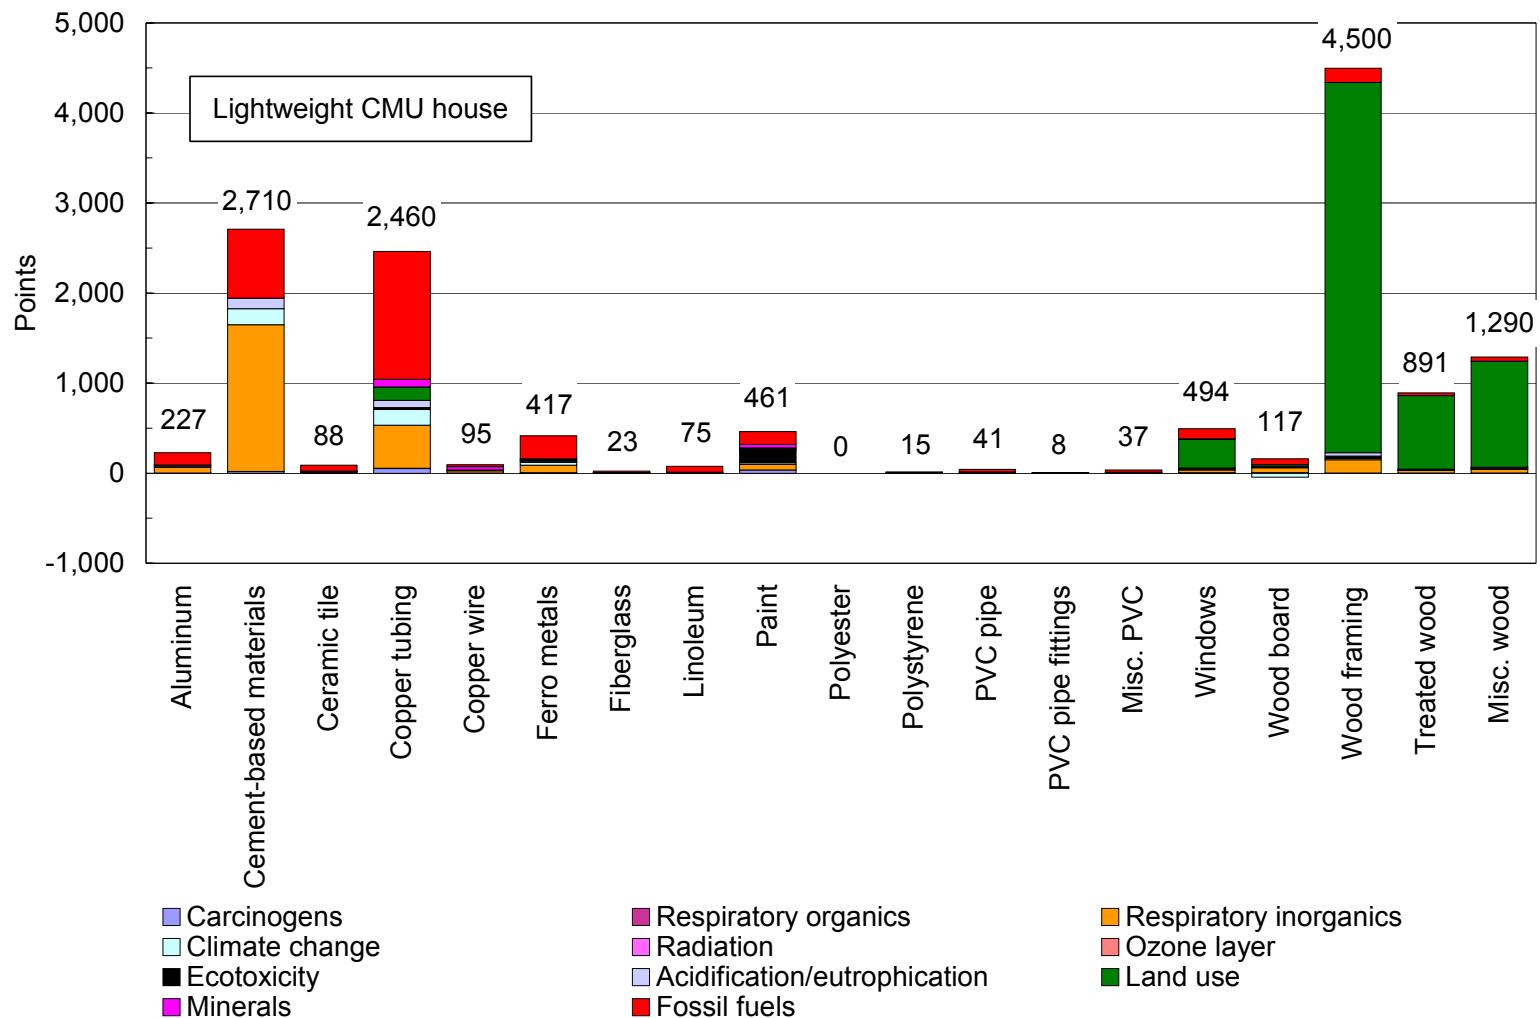

Figure K-2. Single-score life cycle inventory assessment for construction materials in the lightweight CMU house in El Paso (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

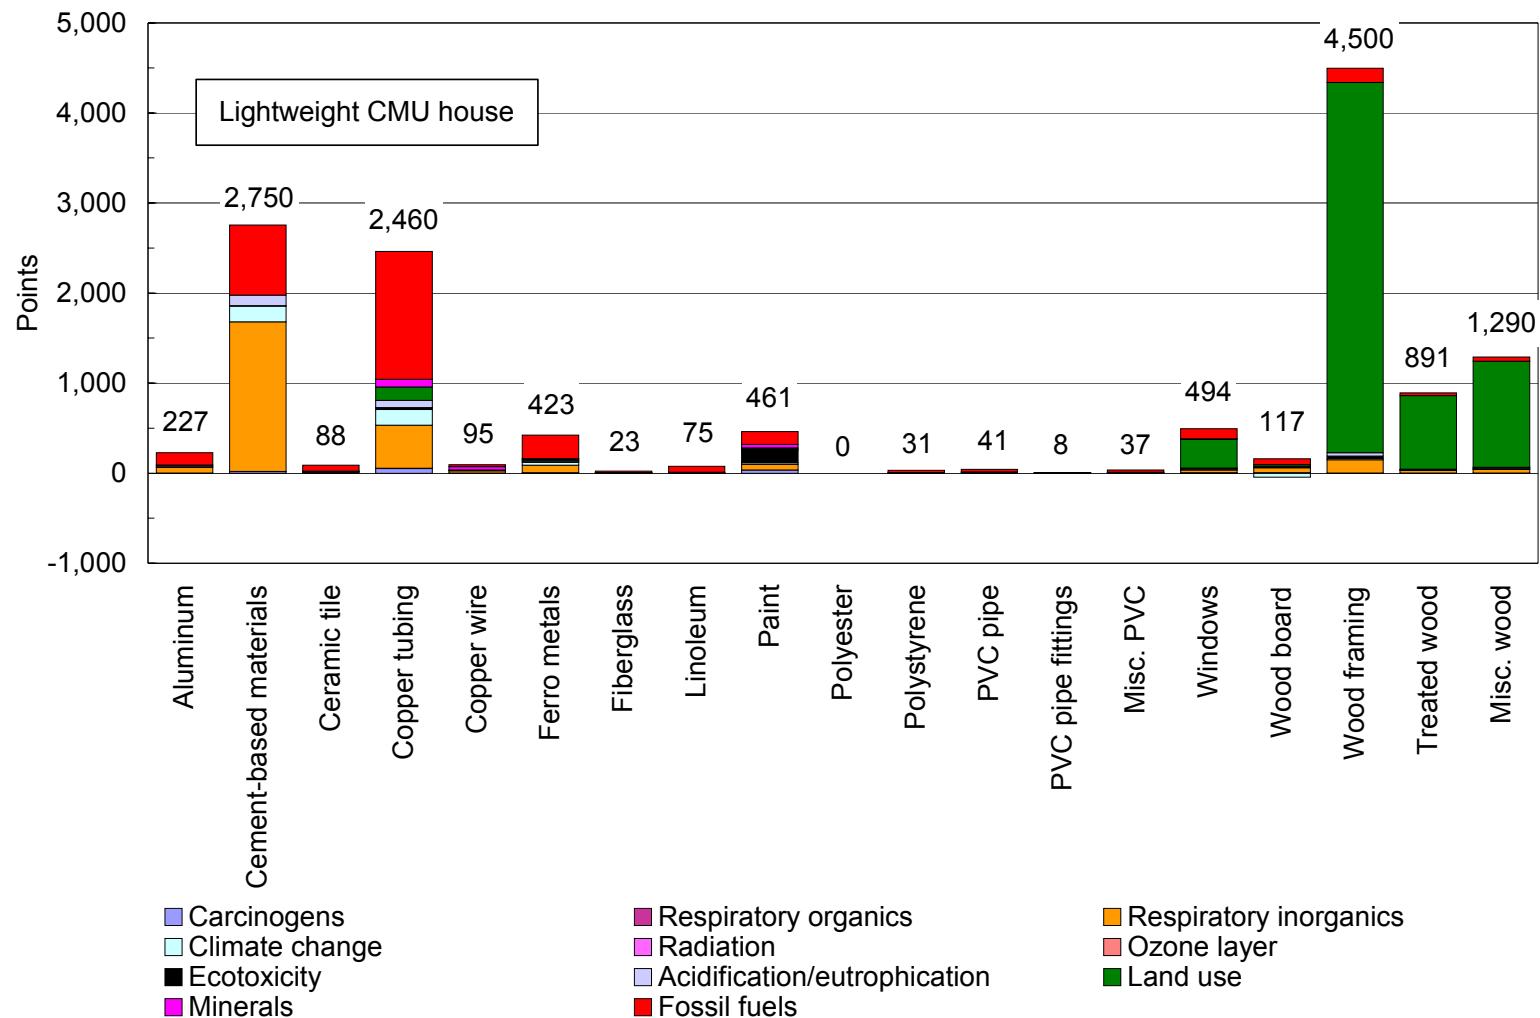

Figure K-3. Single-score life cycle inventory assessment for construction materials in the lightweight CMU house in Knoxville (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

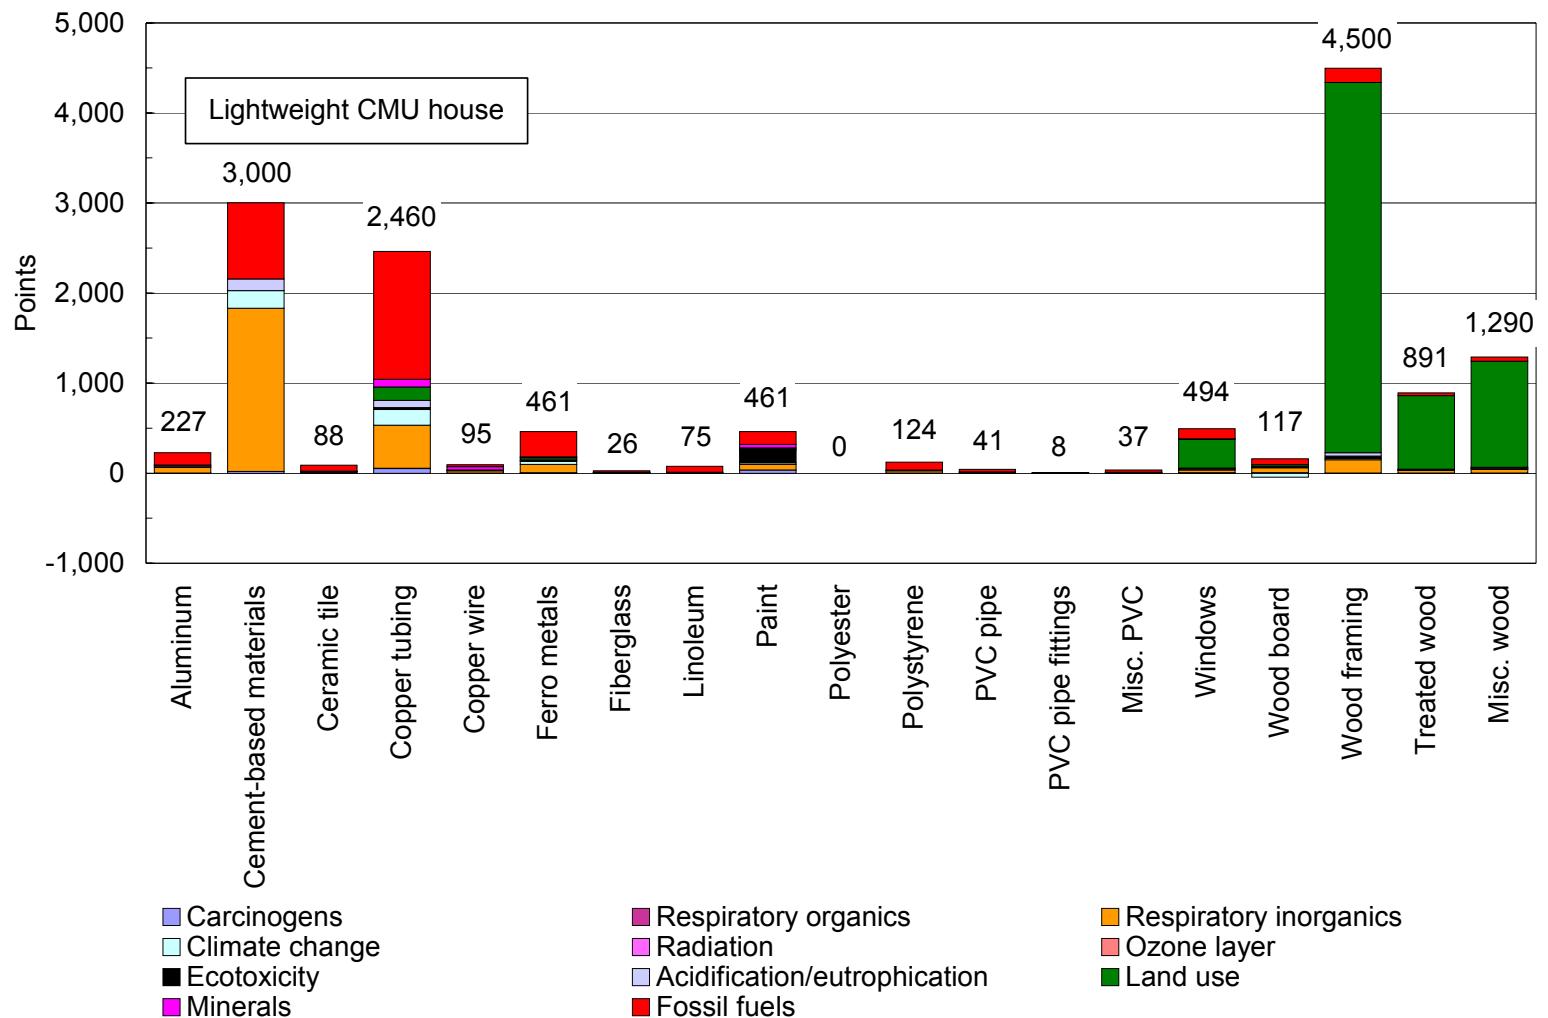

Figure K-4. Single-score life cycle inventory assessment for construction materials in the lightweight CMU house in Providence (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

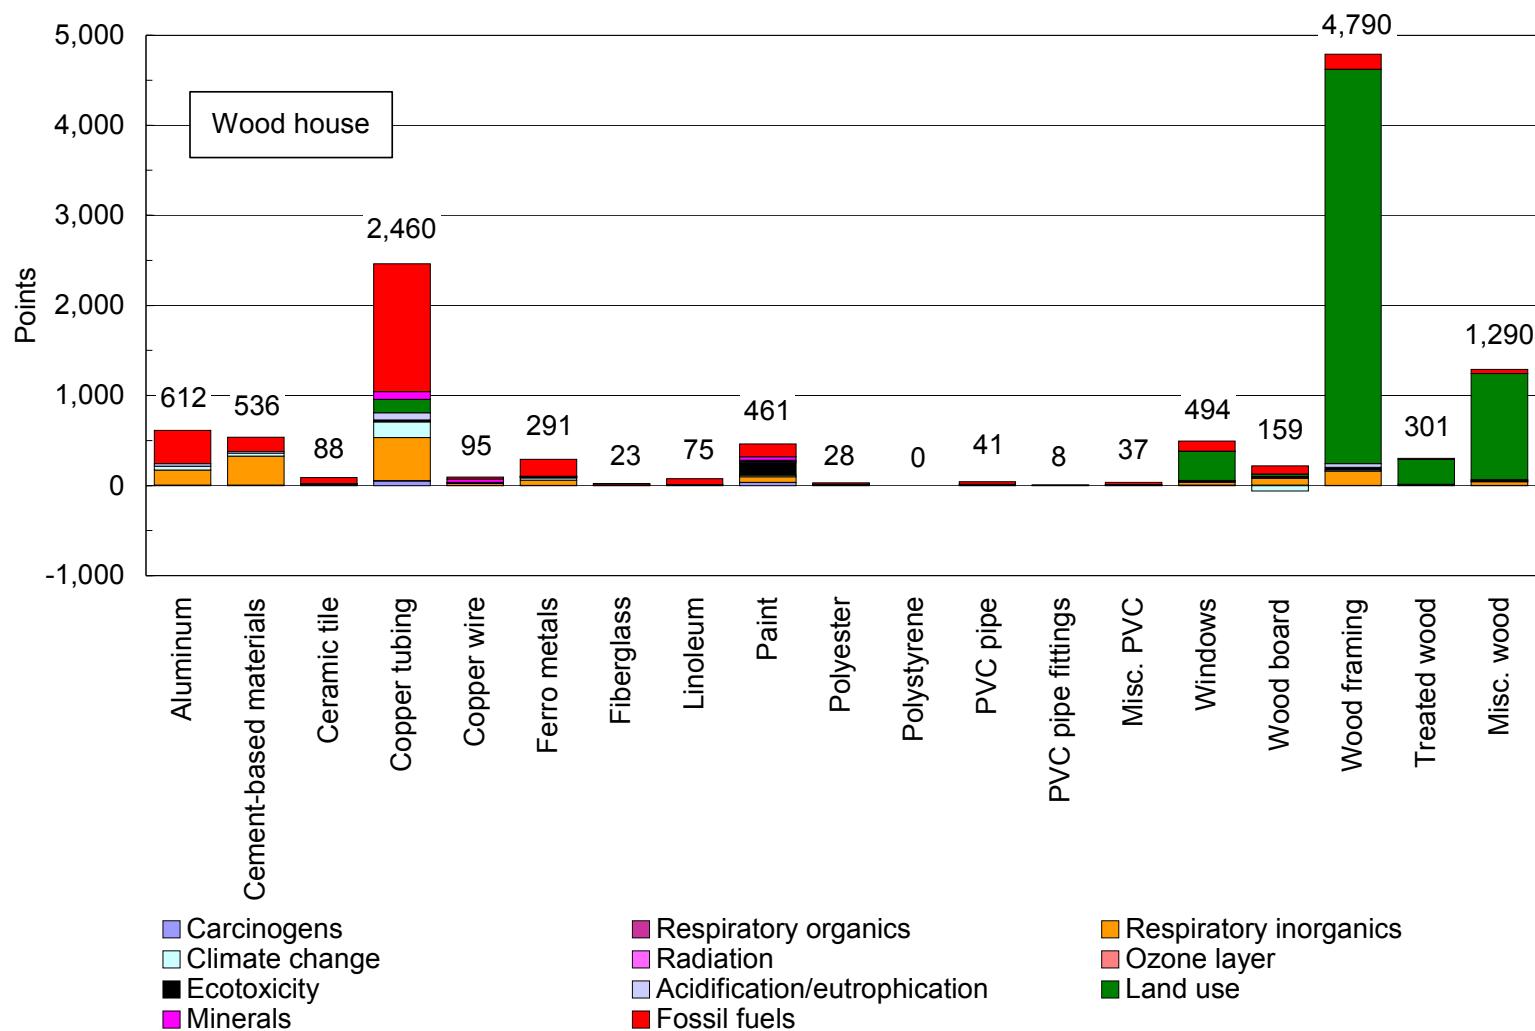

Figure K-5. Single-score life cycle inventory assessment for construction materials in the wood frame house in Tampa (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

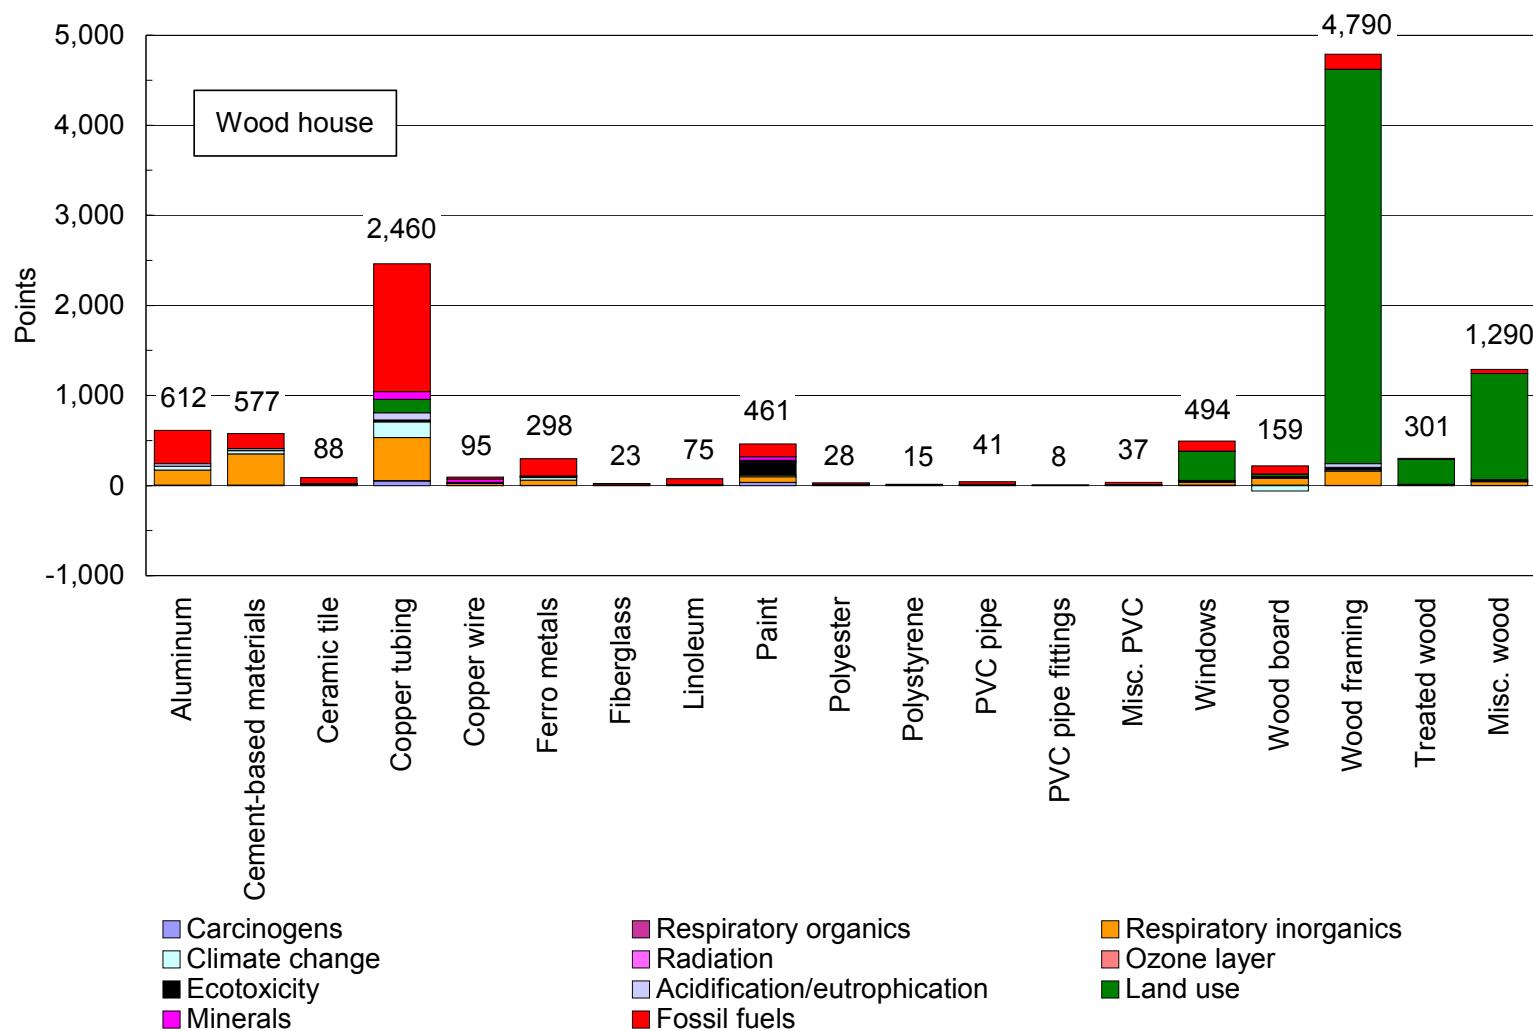

Figure K-6. Single-score life cycle inventory assessment for construction materials in the wood frame house in El Paso (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

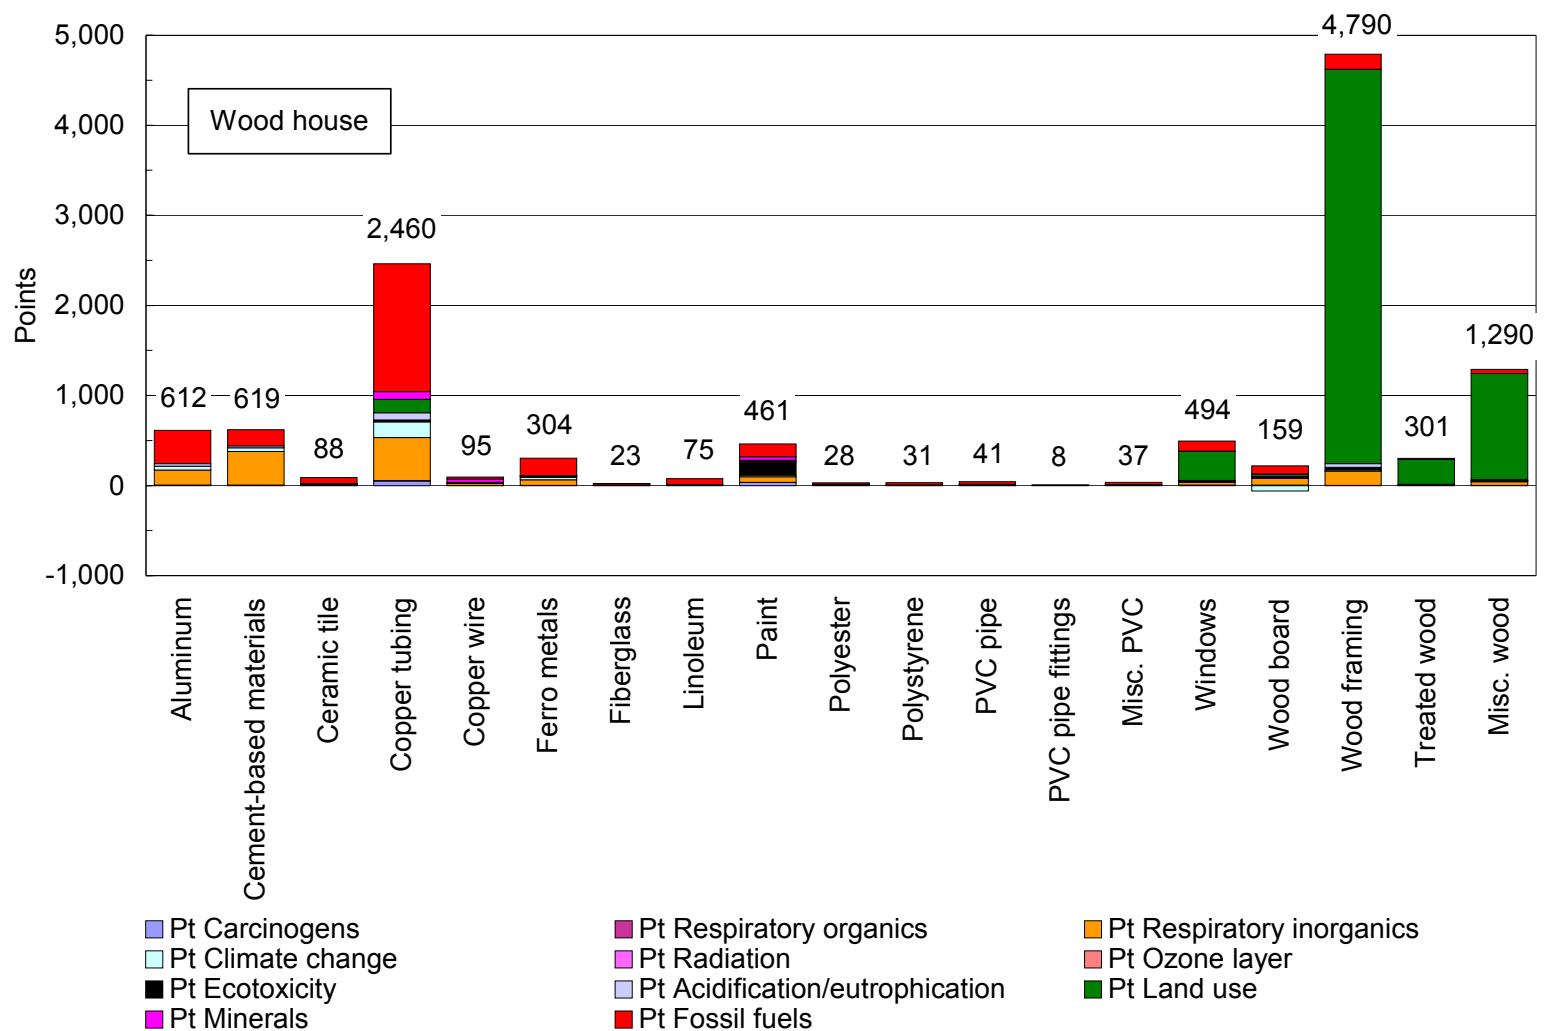

Figure K-7. Single-score life cycle inventory assessment for construction materials in the wood frame house in Knoxville (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.

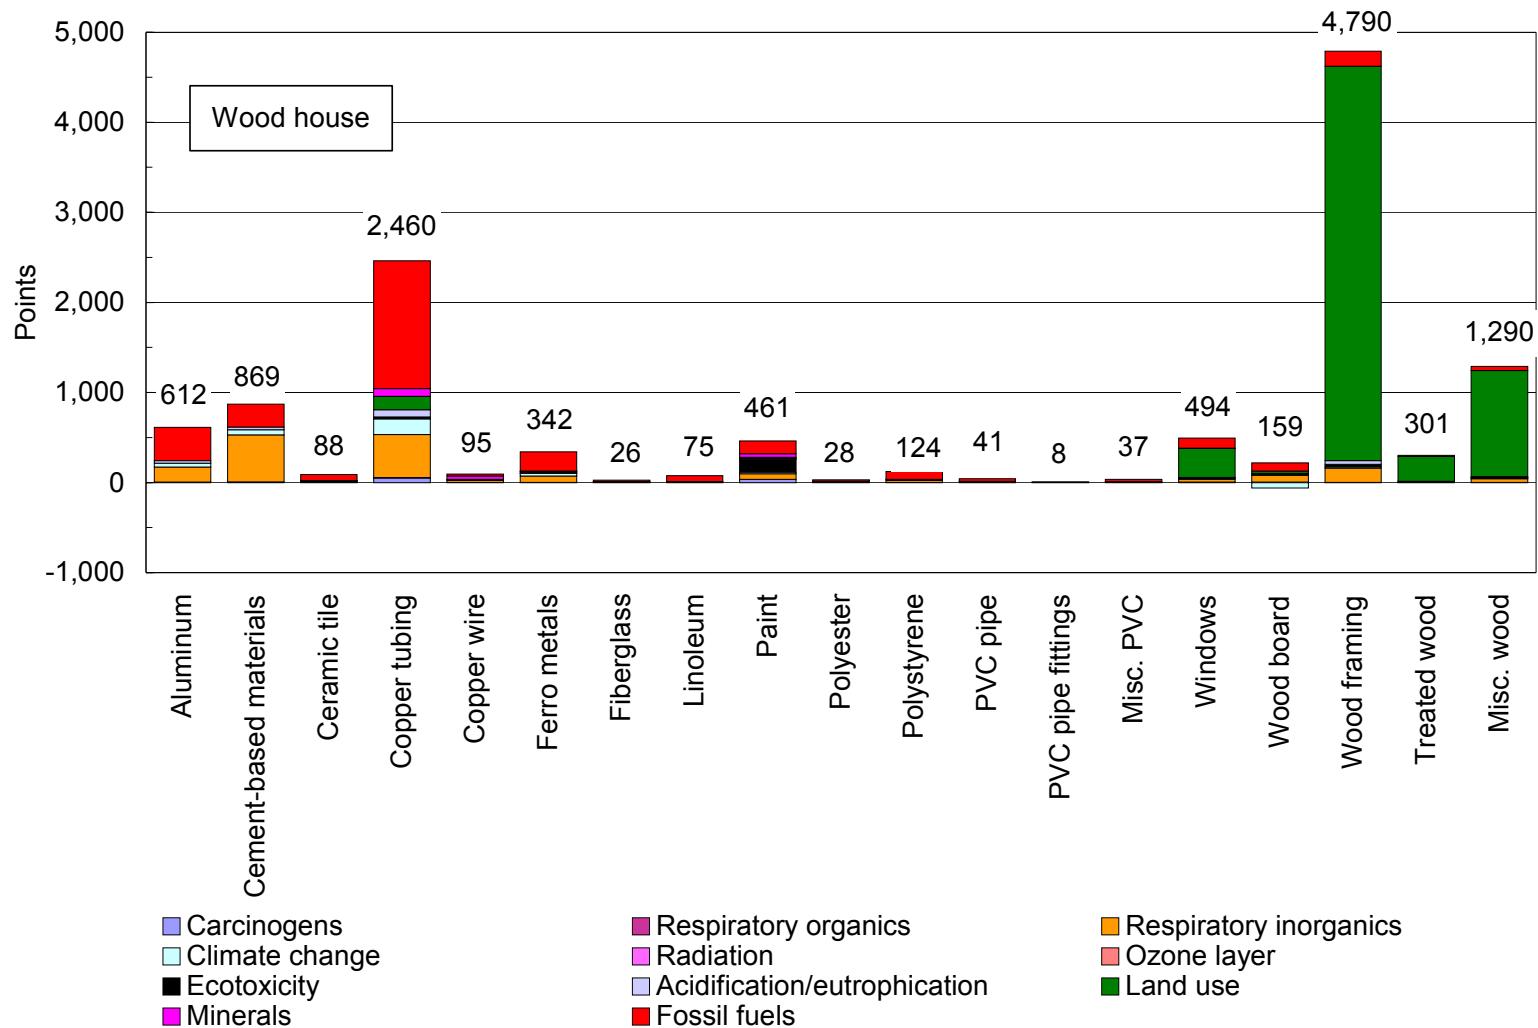

Figure K-8. Single-score life cycle inventory assessment for construction materials in the wood frame house in Providence (output from SimaPro). The data have been normalized and weighted according to the Eco-Indicator 99 method using the Egalitarian perspective.
